Abstract

This paper introduces a novel theoretical framework for understanding institutional dysfunction by applying Richard Dawkins' concepts of extended phenotype and evolutionary palimpsest to legal systems. We identify "memetic pincers" - paired mechanisms where moral inhibitor narratives protect destructive policies from criticism - and demonstrate how these modify the institutional field beyond their immediate domain. Using comparative evidence from rental market controls in Argentina (91% supply reduction, ×12 recovery factor) and Berlin (41% reduction, partial recovery), we show that identical policies produce dramatically different outcomes depending on pre-existing institutional field distortion. We argue that legal systems function as palimpsests where unresolved crises leave memetic layers that act as extended phenotypes, permanently altering the institutional environment. Argentina represents an extreme case where accumulated distortions create a self-reinforcing cycle of dysfunction. The framework makes falsifiable predictions about policy impact amplification, recovery speeds, and institutional collapse thresholds. This synthesis of evolutionary biology and institutional economics offers new insights into why some legal systems become irreformable despite obvious dysfunction.

Keywords: institutional evolution, extended phenotype, path dependency, memetic theory, legal palimpsest, Argentina

1. Introduction

Why do identical policies produce catastrophically different outcomes across jurisdictions? The puzzle is starkest when comparing rental market controls: while Berlin experienced a 41% reduction in rental supply following the 2020 Mietendeckel (DIW Berlin, 2021), Argentina's Law 27,551 triggered a 91% collapse, with supply recovering by a factor of twelve within months of derogation (Reporte Inmobiliario, 2024). This extraordinary divergence cannot be explained by conventional institutional analysis, which would predict similar impacts from similar policies.

This paper proposes a radical reconceptualization: legal systems are not neutral frameworks but evolved organisms carrying the accumulated "genetic memory" of past institutional traumas. Drawing on Dawkins' (2024) concept of organisms as palimpsests - manuscripts where ancient scripts remain partially visible beneath later writings - we argue that legal systems similarly accumulate layers of unresolved institutional crises that permanently modify their operational field.

We introduce the concept of "memetic pincers" - self-protecting policy mechanisms that operate through paired components: (1) a moral inhibitor narrative that blocks criticism ("opposing rent control is supporting speculation"), and (2) a destructive policy that exploits this protection to propagate despite harmful effects. Critically, these pincers exhibit extended phenotype properties (Dawkins, 1982): their effects extend beyond their immediate regulatory domain, permanently modifying the broader institutional field in ways that facilitate their own survival and the emergence of similar dysfunctional patterns.

The Argentine case provides an extreme natural experiment. With documented institutional crises approximately every decade since independence - including hyperinflation (1989-1990), banking system collapse (2001), and serial debt defaults - Argentina's legal system has become a hyperdense palimpsest where multiple unresolved traumas create resonance effects that amplify any policy intervention toward catastrophic outcomes.

Our contribution is threefold: First, we provide the first rigorous application of extended phenotype theory to legal systems, showing how regulatory "genes" modify their environment for survival. Second, we explain why some institutional systems become irreformable despite obvious dysfunction - the accumulated field distortions make the cost of fundamental reform prohibitive. Third, we offer falsifiable predictions about policy impact amplification based on measurable institutional characteristics.

2. Theoretical Framework

2.1 Legal Systems as Evolutionary Palimpsests

Dawkins (2024) describes organisms as palimpsests where "ancient scripts are partially overwritten, still present to be read, though we must look through later writings." This metaphor powerfully captures how legal systems accumulate historical layers that remain operative despite surface-level reforms. Unlike biological evolution, where physical constraints limit retention of obsolete features, legal systems can maintain contradictory or redundant normative layers indefinitely.

Consider the Argentine Constitution: its 1853 foundation established a federal structure modeled on the United States ("quadrupedal" design), yet successive reforms and emergency decrees have created a de facto centralized system ("bipedal" adaptation) without eliminating the federal framework. This generates constant institutional "back pain" - jurisdictional

conflicts, overlapping competencies, and contradictory mandates that mirror the human spine's poor adaptation to upright posture (Dawkins, 2024).

The palimpsest nature of legal systems manifests in three ways:

Structural persistence: Core constitutional arrangements persist even when functionally obsolete, like vestigial organs. Argentina maintains provincial constitutions and legislatures that largely rubber-stamp national decisions, consuming resources without meaningful autonomy.

Normative sedimentation: Each crisis adds regulatory layers without removing previous ones. The 2001 banking crisis spawned regulations that remain active despite changed circumstances, creating compliance costs and confusion.

Temporal compression: Unlike biological evolution's millions of years, legal evolution occurs in decades, creating dense overlapping of unprocessed changes. Argentina has experienced approximately 15 major institutional crises since 1930, each leaving permanent marks.

2.2 Memetic Pincers: The Mechanism of Self-Protecting Dysfunction

We define a memetic pincer as a paired mechanism consisting of:

1. **Inhibitor Component**: A moral narrative that frames opposition as ethically unacceptable
2. **Destructor Component**: A policy that exploits this protection to propagate despite harmful effects

The inhibitor operates like a psychological immune suppressor, preventing the institutional system's normal rejection response to harmful policies. In Argentina's rental market case, the inhibitor "speculation is destroying housing access" made opposing rent control equivalent to supporting speculators, effectively silencing economic criticism.

This mechanism exhibits three critical properties:

Self-reinforcement: The policy's negative effects (reduced supply) appear to validate the inhibitor narrative (landlords are indeed "hoarding"), strengthening the pincer.

Cross-domain propagation: Success in one area facilitates similar pincers elsewhere. Argentina's rent control precedent enabled price controls in other sectors using identical narrative structures.

Resistance to falsification: Empirical failure is reinterpreted as insufficient application rather than flawed theory. When rent control failed, advocates argued for stricter enforcement, not abandonment.

2.3 Extended Phenotype: How Legal Memes Modify Their Environment

Dawkins' (1982) extended phenotype concept - that genes have causal effects beyond the body boundary - applies powerfully to legal systems. Just as beaver dams represent beaver genes' extended phenotype, modifying the environment to favor those genes' survival, legal norms modify the institutional field to ensure their own persistence.

Consider how Argentina's rent control law exhibited extended phenotype properties:

Environmental modification: The law didn't just regulate existing rentals; it fundamentally altered market participant behavior. Landlords preemptively withdrew properties, converted to short-term rentals, or demanded illegal side payments - changes that persisted even after derogation.

Behavioral manipulation: Like Toxoplasma gondii parasites making rats lose fear of cats (Dawkins, 2024), the rent control narrative made market participants act against their interests. Tenants supported policies that reduced available housing, while landlords held empty properties rather than rent them.

Field distortion: The policy modified the institutional field's properties - trust, time preferences, contract enforcement expectations - in ways that favored similar interventionist policies. Post-derogation, the market remained suspicious and defensive.

2.4 Institutional Field Distortion: The Medium Matters

We propose that institutional outcomes depend not just on policies but on the field through which they propagate. This field has measurable properties:

Density: The number of overlapping regulations, institutions, and historical precedents. Argentina's field contains approximately 150+ taxes at national, provincial, and municipal levels (AFIP, 2024), creating extreme regulatory density.

Viscosity: Resistance to change and reform. High viscosity means policies propagate slowly but persist longer. Argentina shows high viscosity - reforms take years to implement but generate immediate defensive reactions.

Memory: The field's tendency to retain past patterns. Argentina's 42% labor informality (INDEC, 2024) represents crystallized memory of past regulatory failures, creating permanent parallel structures.

Resonance: The tendency for disturbances to amplify rather than dampen. In low-resonance fields like Germany, shocks dissipate quickly. In Argentina, each intervention triggers cascading effects across domains.

We formalize this as:

```
Impact = Policy × (1 + FieldDistortion)^Resonance
```

Where `FieldDistortion` captures the accumulated deformations from past crises and Resonance measures cross-domain amplification. This explains why identical policies produce order-of-magnitude different outcomes.

3. Empirical Evidence

3.1 Case Selection and Methodology

We employ a comparative case study design examining rental market controls in Argentina and Berlin - jurisdictions that implemented similar policies (price controls, tenure extensions, deposit limits) but experienced dramatically different outcomes. This natural experiment allows us to hold policy content relatively constant while varying institutional field characteristics.

Data sources include:

- Official statistics from INDEC (Argentina) and Amt für Statistik Berlin-Brandenburg
- Legislative records from both jurisdictions
- DIW Berlin economic research institute reports
- Real estate market data from industry associations

3.2 The Argentine Case: Extreme Field Distortion

Argentina's Law 27,551 (enacted July 2020, repealed December 2023) provides an extreme case of memetic pincer operation with extended phenotype effects:

Inhibitor activation: Parliamentary debates from 2018-2020 show systematic deployment of "speculation" narrative. Opposition to controls was framed as "supporting real estate speculation against families" (HCDN, 2020).

Immediate field response: Unlike Berlin's gradual adjustment, Argentine market participants reacted instantaneously. Between law passage and implementation, rental offerings dropped 62% as landlords preemptively withdrew properties (Reporte Inmobiliario, 2020).

Amplification effects: The policy triggered responses across multiple domains:

- Currency markets: Increased dollar demand as landlords sought value preservation
- Labor markets: Informal employment rose as formal contracts became less attractive
- Construction: New development halted completely in rental segment

Recovery dynamics: Upon derogation (December 2023), supply increased ×12 within six months - from approximately 3,000 to 36,000 units in Buenos Aires (Reporte Inmobiliario, 2024). This extraordinary recovery speed suggests the supply capacity existed but was suppressed by field distortion.

3.3 The Berlin Case: Limited Field Distortion

Berlin's Mietendeckel (February 2020 - April 2021) operated in a fundamentally different institutional field:

Controlled activation: The policy was debated primarily in economic rather than moral terms. While "gentrification" appeared in discourse, it lacked the totalizing moral force seen in Argentina.

Gradual response: Supply declined 41% over twelve months (DIW Berlin, 2021), but through orderly market exit rather than panic withdrawal.

Limited propagation: Effects remained largely contained to rental markets without triggering broader institutional responses.

Partial recovery: Post-invalidation by constitutional court, supply recovered partially but remains "clearly below" pre-control levels (IBB, 2022).

3.4 Quantifying Field Distortion

We construct an Institutional Field Distortion Index (IFDI):

```
IFDI = (Informality × Volatility × Crises) / Trust
```

Where:

- Informality = % informal economy (0.42 Argentina, 0.10 Germany)
- Volatility = σ inflation past 20 years (0.50 Argentina, 0.02 Germany)
- Crises = institutional crises per decade (3.0 Argentina, 0.5 Germany)
- Trust = institutional trust index (0.20 Argentina, 0.60 Germany)

Results:

- Argentina IFDI = 3.15
- Germany IFDI = 0.017

The 185× difference in field distortion correlates with the ~2.2× difference in policy impact (91% vs 41% supply reduction), suggesting a non-linear relationship consistent with our resonance model.

4. Mechanisms and Dynamics

4.1 Historical Accumulation: The Unprocessed Trauma Problem

Argentina's institutional palimpsest contains multiple unresolved layers:

1989-1990 Hyperinflation Layer: Created permanent distrust of domestic currency, leading to dollar-based mental accounting even for local transactions. This "ancient script" makes any price control trigger currency substitution.

2001 Banking Collapse Layer: Established deep distrust of financial institutions. The "corralito" (deposit freeze) created anticipatory behaviors - citizens withdraw funds at the first sign of instability.

Repeated Default Layers: Nine sovereign defaults created expectation of state unreliability. Contract enforcement becomes self-defeating prophecy as parties anticipate state intervention.

Each layer modifies the field's properties. Unlike geological sedimentation, these layers remain active simultaneously, creating interference patterns when activated.

4.2 Cross-Domain Contagion

Memetic pincers exhibit horizontal transmission across regulatory domains:

Labor market contagion: The "anti-speculation" narrative from housing markets spreads to labor: opposing ultra-activity in collective bargaining becomes "supporting exploitation."

Fiscal contagion: Success of moral inhibitors in one domain facilitates tax increases elsewhere. Argentina has 150+ taxes because each new tax is protected by its own moral narrative.

Judicial contagion: Courts internalize inhibitor narratives, making legal challenges ineffective. Judges fear being labeled "pro-speculation" or "anti-worker."

This creates what we term "regulatory sepsis" - the spread of dysfunctional patterns throughout the institutional body.

4.3 Anticipatory Adaptation: The Self-Fulfilling Prophecy

High field distortion creates anticipatory behaviors that amplify policy impacts:

Pre-emptive withdrawal: Market participants exit before policies take effect, creating the scarcity the policy supposedly addresses.

Defensive informality: Actors choose informal arrangements to maintain flexibility, reducing the formal economy the state can regulate.

Hoarding behaviors: Expectation of future controls triggers hoarding, creating shortages that justify controls.

These anticipatory adaptations represent the institutional equivalent of evolutionary "pre-adaptations" - features that evolved for one purpose but enable rapid response to new challenges.

4.4 Resonance and Catastrophic Amplification

When multiple pincers operate simultaneously, they can achieve destructive resonance:

Total Distortion = Σ(Individual Pincers) + Resonance Effects
Argentina currently has active pincers in:

- Housing (rent controls)
- Labor (ultra-activity)
- Currency (capital controls)
- Trade (import restrictions)
- Fiscal (wealth taxes)

Each pincer's frequency of oscillation (boom-bust cycles) approaches synchronization during crises, creating catastrophic resonance that can collapse entire sectors.

5. Implications and Predictions

5.1 Falsifiable Predictions

Our framework makes specific, testable predictions:

Prediction 1: Policy impact scales exponentially with IFDI

- Test: Impact = $\alpha \times \text{Policy} \times (1 + \text{IFDI})^{\beta}$ where $\beta > 1$
- Falsification: Linear relationship or $\beta \leq 1$

Prediction 2: Recovery speed inversely correlates with IFDI

- Test: Recovery_time = k / IFDI
- Falsification: No correlation or positive correlation

Prediction 3: Field distortion exhibits hysteresis

- Test: Post-crisis IFDI > Pre-crisis IFDI even after resolution
- Falsification: Complete return to baseline

Prediction 4: Pincer success predicts similar pincers in other domains

- Test: Temporal clustering of moral inhibitor deployment

- Falsification: Random distribution across time/domains

5.2 Policy Implications

For high-distortion environments:

Simultaneous multi-domain reform: Single-sector reforms fail because field distortion redirects pressure elsewhere. Argentina needs coordinated reform across multiple domains to prevent resonance effects.

Narrative displacement: Direct opposition to inhibitor narratives fails. Successful reform requires alternative moral framings that bypass existing inhibitors.

Field remediation before policy: Reducing field distortion (building trust, reducing informality) must precede specific policy reforms.

Credible commitment mechanisms: External anchors (dollarization, international treaties) may be necessary to overcome anticipatory behaviors.

5.3 Theoretical Contributions

This work contributes to three literatures:

Institutional economics: Explains why identical institutions produce different outcomes, extending path dependency theory with biological insights about constraint accumulation.

Memetic theory: Demonstrates how legal memes exhibit extended phenotype properties, modifying their environment for survival.

Comparative law: Provides framework for understanding why legal transplants fail - the receiving field's distortion determines outcomes more than the transplanted law's content.

6. Limitations and Future Research

Several limitations merit acknowledgment:

Measurement challenges: Quantifying field distortion requires proxy measures. Direct measurement of institutional "viscosity" or "resonance" remains methodologically challenging.

Causality: While we document correlation between field distortion and policy outcomes, establishing causation requires additional natural experiments or instrumental variables.

Scope conditions: Our framework may apply primarily to middle-income countries with histories of institutional instability. Application to developed or very poor countries requires modification.

Time horizons: We observe short-term dynamics (months to years) but long-term evolutionary trajectories (decades to centuries) remain speculative.

Future research should:

- Test predictions across more countries and policies
- Develop better field distortion metrics
- Explore remediation strategies for high-distortion environments
- Model resonance effects mathematically
- Study how fields can be "reset" after extreme distortion

7. Conclusion

Legal systems are not neutral frameworks but evolved organisms carrying the accumulated memory of past institutional traumas. Like biological palimpsests, they retain ancient scripts that constrain present adaptation. The concept of memetic pincers - self-protecting dysfunctional policies - combined with extended phenotype theory explains how regulations modify their institutional environment to ensure their own survival, creating fields so distorted that reform becomes impossible.

Argentina represents an extreme case where approximately 15 institutional crises since 1930 have created a hyperdense palimpsest. Each unresolved crisis added a layer of distortion, modifying the field's properties - its density, viscosity, memory, and resonance - in ways that amplify any policy intervention toward catastrophic outcomes. The ×12 recovery factor in rental markets reveals not resilience but the extent of suppression under field distortion.

This framework resolves puzzles in institutional economics: why identical policies produce radically different outcomes, why some societies seem trapped in dysfunction despite obvious solutions, and why institutional transplants consistently fail. The answer lies not in the policies or institutions themselves but in the field through which they propagate.

The implications are sobering. High field distortion may represent an evolutionary dead end - a state where the accumulated costs of past adaptations make fundamental reform prohibitively expensive. Like the giraffe's recurrent laryngeal nerve, which cannot be "fixed" without fatal disruption to embryological development, heavily distorted institutional fields may be condemned to live with their accumulated dysfunctions.

Yet understanding these dynamics opens possibilities for intervention. If we cannot eliminate field distortion, we might still navigate it. Recognizing that policies are waves propagating

through media of varying properties allows more realistic calibration of reforms. The extraordinary Argentine case, far from being merely pathological, reveals fundamental truths about how legal systems evolve, accumulate dysfunction, and occasionally, against all odds, survive.
