Beyond WEIRD Bias: Why Token-Based Legal AI Cannot Model Post-Colonial Compliance Dynamics

An Evolutionary Framework Integrating Henrich's Institutional Origins, IusSpace Morphology, and Concept-Based Architectures

ABSTRACT

Joseph Henrich's *The WEIRDest People in the World* (2020) demonstrates that Western psychology—individualistic, impersonally prosocial, guilt-based—emerged from the Catholic Church's Marriage and Family Program (400-1200 CE) dissolving extended kin networks. This historical accident, affecting 12% of humanity, enabled specific institutional forms: impersonal markets, rule-based bureaucracy, constitutional governance. The remaining 88% retained relationship-based, kin-intensive, shame-oriented psychology and corresponding particularistic institutions.

This paper demonstrates that legal AI systems trained on WEIRD legal corpora cannot serve non-WEIRD jurisdictions because they encode institutional assumptions requiring WEIRD psychology. The formal/informal compliance gap—divergence between law-as-written and law-as-enforced—averages 5.4% in WEIRD societies versus 31.2% in non-WEIRD societies (difference: 25.8 percentage points, $p < 0.0001$, Cohen's $d = 3.749$). This gap is not "weak institutions" but rational adaptation: populations lacking WEIRD psychology cannot sustain WEIRD institutional forms without systematic discount.

We formalize this through successive multiplicative layers: behavioral framing effects (Layer 1, approximately 12% universal) multiply by institutional legitimacy discount (Layer 2, approximately 3× in non-WEIRD contexts reflecting WEIRD-institution/non-WEIRD-psychology mismatch) and institutional volatility (Layer 2b), producing compound divergence. Token-based language models fragment trans-jurisdictional legal concepts, lack explicit parameters for institutional discount, and cannot perform counterfactual reasoning on enforcement dynamics—failures that are architectural, not remediable through scaling.

Building on this author's prior frameworks (IusSpace 12-dimensional morphology mapping legal systems; Iusmorfos adaptive coefficients predicting reform implementation with 87.4% accuracy across 18 reforms in 13 countries; ESS game-theoretic analysis of legal persistence), we introduce LegalGapDB: first systematic database documenting formal/informal divergence using official sources (20 validated cases, Argentina 2020-2025; target: 500 cases, 20 jurisdictions).

We propose Small Concept Models (SCM) as architecturally superior alternative. Operating in sentence-embedding space with explicit jurisdiction-specific parameters, SCM preserve conceptual unity across languages and enable parametric reasoning impossible for token-based systems. Implementing Meta AI's París mixture-of-experts architecture (first worldwide adaptation from text-to-image to text-to-concept reasoning), París-SCM achieves 81% accuracy on specialist legal queries versus 67% for monolithic SCM-1.6B and 58% for GPT-4, with modular scalability enabling addition of new domains without catastrophic forgetting.

Henrich explains why WEIRD/non-WEIRD divergence exists. This paper measures how much (31.2% gap), formalizes how it operates (multiplicative layers), maps where systems are positioned (IusSpace), predicts reform outcomes (Iusmorfos), and demonstrates that concept-based architectures with mixture-of-experts specialization provide solution for legal AI serving the 88% of humanity living under non-WEIRD institutional arrangements.

Methodological transparency: Mathematical formalizations developed through collaboration between author (legal domain expert) and large language models (notation assistance). All conceptual frameworks, empirical observations, theoretical interpretations originate from author's independent research.

Keywords: Legal AI, WEIRD bias, Henrich, compliance gaps, post-colonial law, concept models, adaptive coefficients, institutional psychology, IusSpace, mixture of experts, París architecture

1. INTRODUCTION: THE 88% PROBLEM

1.1 Henrich's Revelation and Legal AI's Blind Spot

In "The WEIRDest People in the World" (2020), Joseph Henrich traces a historical accident that transformed European psychology and, consequently, the world's institutional landscape. Between 400-1200 CE, the Catholic Church implemented its Marriage and Family Program (MFP): prohibiting cousin marriage, polygamy, adoption, and other practices that sustained intensive kinship networks. Over centuries, this dissolved the extended family structures that had organized human societies for millennia.

The result was unprecedented psychological transformation. Western Europeans became WEIRD: Western, Educated, Industrialized, Rich, Democratic. More precisely, they became individualistic (prioritizing personal goals over kin obligations), impersonally prosocial (trusting strangers in one-shot transactions), guilt-based (internalizing norms rather than responding to shame), and analytically-minded (focusing on objects' properties rather than relationships). Henrich documents this is not "universal human nature" but recent deviation affecting perhaps 12% of global population—overwhelmingly Western Europeans and their settler colonies (Henrich 2020: 22-29).

Critically for legal systems, WEIRD psychology enabled specific institutional forms that could not have emerged otherwise:

Impersonal markets require trusting strangers in one-shot transactions—psychologically costly for populations embedded in intensive kinship networks where exchange occurs through repeated interactions with known partners (Henrich 2020: 335-367).

Rule-based bureaucracy requires following abstract procedures over personal loyalty—violating fundamental kin-based obligations in non-WEIRD societies where protecting family supersedes impersonal rules (Henrich 2020: 403-427).

Voluntary associations require forming organizations with non-kin based on shared interests—unnatural for populations where social organization flows from kinship rather than voluntary affiliation (Henrich 2020: 368-402).

Constitutional governance requires accepting constraints on power from impersonal law—requiring trust that abstract rules will be enforced even against powerful actors, a trust that developed over centuries in WEIRD contexts but remains fragile in non-WEIRD societies (Henrich 2020: 428-456).

These institutional forms emerged organically from WEIRD psychology over centuries. When exported to non-WEIRD societies through colonialism, they were adopted formally (constitutions written, codes enacted, bureaucracies established) but operate differently because the underlying psychology never transformed. The 88% of humanity that never experienced MFP transformation retained kin-based, relationship-oriented, particularistic, shame-based psychology—not as "underdevelopment" but as the ancestral human condition from which WEIRD psychology recently deviated (Henrich 2020: 457-474).

This has profound implications for legal artificial intelligence. Current systems train predominantly on WEIRD legal corpora: United States federal law, English case law, European Union regulations. They learn patterns from legal systems designed by and for populations with WEIRD psychology. When deployed in non-WEIRD contexts—the 88% majority—they fail systematically because they encode institutional assumptions requiring psychological substrate that doesn't exist.

This paper documents that failure empirically, explains it theoretically through integration of Henrich's historical framework with this author's prior work on legal evolution, and proposes architectural solutions enabling legal AI to serve non-WEIRD populations on their actual institutional terms rather than approximating WEIRD structures that will inevitably fail.

1.2 From Historical Causation to Quantified Divergence

Henrich explains why WEIRD and non-WEIRD institutional arrangements differ. This paper measures how much they differ in legal compliance.

On December 11, 2024, Meta AI published "Large Concept Models" (Barrault et al. 2024) proposing architectures operating on semantic concepts rather than lexical tokens. The same week, this author completed fieldwork documenting systematic divergence between written labor law and actual compliance in Argentina: 42 percentage points separating statutory mandate from observable reality (INDEC Q4 2024).

The formal/informal compliance gap—divergence between law-as-written and law-as-enforced—averages 5.4% in WEIRD societies and 31.2% in non-WEIRD societies (Lerer 2025b, Iusmorfos V4.0 validation across 18 reforms in 13 countries, 2015-2024). This 25.8

percentage point difference ($p < 0.0001$, Cohen's $d = 3.749$) represents not data scarcity but structural reality predicted by Henrich's framework: WEIRD institutions operating in non-WEIRD psychological contexts sustain with systematic discount.

The gap is not dysfunction. It is adaptation. When Spanish colonial authorities implemented "se acata pero no se cumple" (one obeys but does not comply) as standard administrative practice in the 1590s (Brading 1991), they were not resisting modernity but solving coordination problem: how to acknowledge distant authority (preserving legitimacy) while preserving local power relationships (maintaining social function). This practice persists 430 years later because the underlying psychological mismatch persists: WEIRD legal institutions grafted onto non-WEIRD populations.

1.3 The Core Paradox: Good Predictions, Wrong Structure

Consider a superficially puzzling result. When this author prompted Claude Sonnet 4.5—one of the most capable language models as of October 2025—to predict Argentine labor formalization rates without providing LegalGapDB data, the model responded:

"Based on literature about labor informality in Latin America: Argentina has historically high informality (~35-45% according to regional studies)... Estimation: 60-70% compliance"

Actual rate from official statistics: 58% (INDEC Q4 2024). Model's prediction: 60-70%. Error: approximately 5 percentage points.

Problem solved? No. The model arrived at approximately correct aggregate through distributional learning from regional informality studies. It cannot:

1. **Explain causal structure** (WEIRD institutions operating in non-WEIRD psychological context → Layer 2 institutional discount)
2. **Provide jurisdiction-specific parameters** (why Argentina -0.35 vs Chile -0.15)
3. **Enable counterfactual reasoning** ("if Argentina increases enforcement 50%, gap becomes?")
4. **Update in real-time** (Argentine DNU vote October 8, 2025—model unaware)
5. **Represent constraints** (which reforms viable in IusSpace, which not)

For legal AI serving the 88% of humanity in non-WEIRD societies, these capabilities are not optional enhancements but fundamental requirements. Approximate aggregate predictions are insufficient—and potentially dangerous—when legal compliance counseling determines whether businesses survive, reforms succeed, or investments are protected.

Henrich provides the why. This paper provides the how much, the how, and the architectural solution.

1.4 What This Paper Contributes

This work makes five distinct contributions:

Theoretical synthesis: Integrates Henrich's (2020) historical explanation of WEIRD psychology with this author's prior frameworks: IusSpace 12-dimensional morphology (Lerer 2025b), Iusmorfos adaptive coefficients (Lerer 2025b), evolutionary stable strategy analysis (Lerer 2025a), and Rootfinder constraint mapping. The result: formalized successive multiplicative layers model showing that behavioral framing (Layer 1) × institutional discount reflecting WEIRD/non-WEIRD psychology mismatch (Layer 2) × institutional volatility (Layer 2b) produces compound divergence architecturally unlearnable from text corpora.

Empirical measurement: Presents LegalGapDB, first systematic database documenting formal/informal divergence with official source verification (20 validated cases, Argentina 2020-2025; gaps ranging 17-57% across domains). Combined with Iusmorfos validation achieving 87.4% prediction accuracy across 18 reforms in 13 countries, demonstrates compliance dynamics are parametric (jurisdiction-specific coefficients) not distributional (corpus-learnable patterns).

Architectural innovation: Proposes Small Concept Models operating in sentence-embedding space with explicit enforcement parameters, outperforming token-based systems 100× larger on cross-jurisdictional reasoning and enforcement prediction. Implements París-SCM—first worldwide adaptation of Meta AI's París mixture-of-experts from text-to-image to text-to-concept reasoning—achieving 81% accuracy on specialist legal queries versus 67% monolithic and 58% GPT-4.

Methodological protocols: Establishes reproducible procedures for measuring enforcement gaps using only public official sources, enabling collaborative expansion without proprietary dependencies.

Operational deployment: Provides fully functional París-SCM with three legal domain experts (Law 27.401 anti-corruption, public procurement, labor law), learned router (94% accuracy), modular architecture enabling addition of new domains without catastrophic forgetting.

1.5 The Engelbart Connection: Networks Not Chains

Patent attorney Brandon Barney observed that Douglas Engelbart's 1962 "Augmenting Human Intellect"—arguing that linear text forces serial reasoning when reality operates as conceptual networks—captures why token-based legal AI fails for non-WEIRD systems.

Consider "se acata pero no se cumple"—430 years of institutional practice crystallized in six words. This is not word sequence but conceptual network with properties: historical origin (Council of Indies 1596), enforcement discount factor ($\gamma \approx 3.5$ for Argentina), jurisdictional variation (stronger in Spanish America than Portuguese Brazil), interaction effects (amplifies behavioral framing Layer 1).

Token-based models fragment this into ["se", " ac", "ata", " pero", " no", " se", " c", "umple"], learning correlations but not representing the network node with parameters. Engelbart argued progress requires tools matching reality's topology. Token-based legal AI imposes serial processing on networked phenomena. The multiplication Layer 1 × Layer 2 exemplifies network effects invisible to serial token processing.

Henrich's framework is fundamentally about networks: how intensive kinship networks (non-WEIRD) differ from voluntary association networks (WEIRD), and how this difference produces different institutional equilibria. Legal AI for non-WEIRD contexts requires architectural matching this networked reality—concept-based systems with explicit relational parameters, not token chains approximating through distributional learning.

1.6 Roadmap

Section 2 reviews literature: Henrich's WEIRD framework (extended treatment), behavioral law and economics, post-colonial legal studies, evolutionary game theory. Section 3 formalizes successive multiplicative layers integrating Henrich with IusSpace and ESS frameworks. Section 4 presents LegalGapDB and Iusmorfos empirical validation. Section 5 analyzes token-based LLM structural failures. Section 6 presents SCM and París-SCM implementation. Section 7 discusses implications. Section 8 concludes.

---

2. LITERATURE REVIEW: FOUR INTELLECTUAL TRADITIONS

2.1 Henrich's WEIRD Framework: The Historical Foundation

2.1.1 The Marriage and Family Program: Institutional Shock

Joseph Henrich's "The WEIRDest People in the World" (2020) provides the historical account explaining why 12% of humanity developed peculiar psychology enabling distinctive institutional forms. The story begins not with individual psychology but with institutional intervention: the Catholic Church's Marriage and Family Program (MFP).

Starting around 400 CE and intensifying through 1200 CE, the Church systematically prohibited practices sustaining intensive kinship networks:

Cousin marriage: Banned progressively from first cousins (400s) to sixth cousins by 1100s. This prevented wealth consolidation within lineages and forced outmarriage, gradually dissolving extended family structures (Henrich 2020: 176-184).

Polygamy and concubinage: Prohibited, forcing monogamy even among elites who could afford multiple wives. This prevented powerful men from forming alliance networks through strategic marriages (Henrich 2020: 185-189).

Adoption and arranged marriages: Restricted or prohibited, limiting families' ability to strategically incorporate outsiders or form inter-lineage alliances (Henrich 2020: 189-192).

Inheritance to kin: Encouraged bequests to Church rather than extended family, further weakening lineage continuity (Henrich 2020: 192-197).

The Church's motivation was institutional self-interest: by dissolving kinship networks, it positioned itself as primary social institution filling the void. But the unintended consequence was psychological transformation taking centuries to manifest (Henrich 2020: 197-203).

2.1.2 From Kinship Dissolution to WEIRD Psychology

As intensive kinship dissolved over generations, European populations developed unprecedented psychological traits (Henrich 2020: 204-245):

Individualism: Freed from obligations to extended kin, individuals began pursuing personal goals and forming voluntary associations based on shared interests rather than birth. Medieval European guilds, universities, and merchant associations exemplify organizational forms impossible in intensive kinship societies where clan membership determines participation (Henrich 2020: 246-282).

Impersonal prosociality: With less investment in maintaining reputation within stable kin networks, Europeans developed willingness to trust strangers in one-shot transactions. This

enabled impersonal markets where parties trade based on contractual terms rather than relationship history (Henrich 2020: 335-367).

Guilt-based morality: Intensive kinship societies use shame (external social disapproval) to enforce norms. WEIRD populations internalized norms as guilt (self-directed negative emotion), enabling norm compliance even without social monitoring—critical for rule-based bureaucracy and constitutional governance (Henrich 2020: 283-309).

Analytical thinking: Kinship-intensive societies emphasize holistic thinking focused on relationships between entities. WEIRD populations developed analytical thinking focused on objects' intrinsic properties independent of context—enabling abstraction required for formal law, scientific method, and bureaucratic categorization (Henrich 2020: 310-334).

2.1.3 From WEIRD Psychology to WEIRD Institutions

These psychological traits enabled institutional forms that could not have emerged otherwise (Henrich 2020: 368-456):

Impersonal markets: Require trusting strangers in one-shot exchanges based on contractual terms rather than relationship history. For populations embedded in intensive kinship where exchange occurs through repeated interactions with known partners, this is psychologically costly and economically risky. Markets emerged gradually in Western Europe as WEIRD psychology made impersonal trust feasible (Henrich 2020: 335-367).

Rule-based bureaucracy: Requires following abstract procedures even when they conflict with obligations to family or patrons. For non-WEIRD populations, protecting kin supersedes impersonal rules—violating this is moral failure not ethical compliance. Weber's "rational-legal" bureaucracy presupposes guilt-based individuals who internalize impersonal rules (Henrich 2020: 403-427).

Voluntary associations: Medieval European guilds, universities, and eventually modern corporations, political parties, and NGOs exemplify organizations formed through voluntary affiliation rather than kinship. For populations where social organization flows from kin networks, forming associations with non-kin based on shared interests violates natural social order (Henrich 2020: 368-402).

Representative democracy and constitutional governance: Require accepting that abstract rules constrain power, that representatives act for strangers not kin, and that electoral outcomes bind losers. This requires trust that institutions will function

impersonally—trust developed over centuries in WEIRD contexts where kinship no longer determined political allegiance (Henrich 2020: 428-456).

2.1.4 The Non-WEIRD Majority: Not Underdevelopment But Alternative Equilibrium

Critically, Henrich demonstrates non-WEIRD institutional arrangements are not failed attempts to replicate WEIRD institutions but alternative equilibria suited to different psychology (Henrich 2020: 457-474):

Intensive kinship systems provide insurance against risk, enforce contracts through reputation in repeated interactions, and coordinate collective action through clan structures. They are optimized for environments where centralized state capacity is weak or absent—historically the human norm (Henrich 2020: 44-72).

Shame-based morality is more efficient for norm enforcement when social monitoring is feasible (small groups, stable membership). Guilt is costlier to maintain (requires internal emotional regulation) and emerged in WEIRD contexts where kinship dissolution made social monitoring less effective (Henrich 2020: 283-309).

Holistic thinking accurately captures relational realities in contexts where success depends on navigating complex social networks. Analytical thinking is advantageous when optimizing for object properties independent of social context—useful for science and bureaucracy but not superior for all domains (Henrich 2020: 310-334).

Particularistic institutions (treating individuals differently based on relationship) are not corruption but rational adaptation when universal rules would disadvantage one's kin-based insurance network. Impersonal universalism is luxury affordable when state institutions substitute for kinship safety nets (Henrich 2020: 457-461).

The 88% of humanity that never experienced MFP transformation did not "fail to modernize"—they retained psychological and institutional arrangements that served humanity successfully for millennia. WEIRD psychology is recent deviation, not evolutionary destiny (Henrich 2020: 22-29).

2.1.5 Colonial Transplantation: Institutional Grafts on Non-WEIRD Psychology

When European colonial powers exported WEIRD institutions globally (1500s-1900s), they created profound mismatch. Written constitutions proclaimed individual rights, impersonal bureaucracy, rule-based administration. But populations lacking WEIRD psychology could not sustain these institutions without systematic adaptation (Henrich 2020: 461-467).

The result was not institutional failure but institutional transformation. Brading (1991) documents "se acata pero no se cumple" (one obeys but does not comply) as standard Spanish colonial administrative practice from 1590s onward: formal acknowledgment of royal authority combined with practical non-enforcement when enforcement conflicted with local power relationships.

This was not resistance or corruption but rational coordination: acknowledge formal rules (preserving legitimacy) while adjusting implementation (preserving function). Colonial viceroys explicitly instructed "If royal cédulas contain provisions impossible to execute, represent the difficulty to His Majesty, but in the meantime suspend execution" (Brading 1991: 287).

Henrich's framework explains why this practice was necessary and why it persists 430 years later. WEIRD institutions require WEIRD psychology. Imposing them on non-WEIRD populations without psychological transformation produces systematic gap between formal rules and actual enforcement. This is not temporary transition but stable equilibrium reflecting underlying psychology-institution mismatch.

2.1.6 Implications for Legal AI

Henrich's framework has profound implications for legal artificial intelligence:

1. WEIRD legal training data encodes WEIRD institutional assumptions. US case law, English common law, EU regulations—these corpora document legal systems designed by and for populations with WEIRD psychology. They assume impersonal prosociality, guilt-based compliance, analytical reasoning, and trust in abstract rules. Models trained on these corpora learn patterns appropriate for 12% of humanity.

2. Non-WEIRD legal systems operate through different logics. When Esquirol (2008) describes Latin American "legal fables" or Rodríguez Garavito (2011) documents Colombian systematic non-enforcement, they observe surface manifestations of deeper reality: these societies never underwent MFP transformation. Their populations retain kin-based, relationship-oriented, shame-based, particularistic psychology producing different institutional equilibria.

3. The formal/informal gap is not dysfunction but adaptation. WEIRD institutions grafted onto non-WEIRD populations sustain with discount reflecting psychology-institution mismatch. The gap is predictable, quantifiable (Layer 2 multiplier $\gamma \approx 3\times$ in Latin America, validated empirically in Section 4), and rational response to institutional transplant.

4. Legal AI for non-WEIRD contexts requires different architecture. Token-based models trained on WEIRD corpora approximate WEIRD institutional logic. They cannot represent the causal structure producing non-WEIRD compliance gaps because that structure is not in text—it's in psychology-institution interaction Henrich documents historically. This requires explicit parametric representation, not distributional learning.

The remainder of this literature review connects Henrich's historical explanation to complementary frameworks: behavioral economics (universal framing effects), post-colonial legal theory (institutional persistence mechanisms), and evolutionary game theory (why bad equilibria resist displacement).

2.2 Behavioral Law and Economics: Layer 1

Kahneman & Tversky (1979) demonstrated that decision-making under uncertainty systematically deviates from expected utility maximization through framing effects—how choices are presented alters behavior even when substantive options remain identical. Thaler & Sunstein (2008) applied these insights to law and policy through "libertarian paternalism," documenting that choice architecture influences compliance without coercion.

Key empirical findings:

- Automatic enrollment in retirement plans increasing participation from 49% to 86% (Madrian & Shea 2001)
- Opt-out organ donation systems achieving 90%+ registration versus 15% for opt-in (Johnson & Goldstein 2003)
- Default printer settings reducing paper consumption by 15% (Egebark & Ekström 2016)

Sunstein (2000) argues law operates through mandates (do X or face sanction Y) and architecture (design environments where X becomes path of least resistance). Meta-analysis of nudge interventions (Hummel & Maedche 2019) shows median effect size $\beta \approx 0.12$, suggesting behavioral framing accounts for approximately 10-15% variance in compliance rates when formal penalties remain constant.

Connection to Henrich: These behavioral effects are largely universal—they operate in both WEIRD and non-WEIRD populations. They constitute Layer 1: baseline behavioral variance present regardless of institutional context. But Layer 1 interacts with psychology-institution

mismatch (Layer 2) multiplicatively rather than additively, producing compound effects documented in Section 3.

2.3 Post-Colonial Legal Theory: Layer 2 Mechanisms

Brading (1991) traces "se acata pero no se cumple" to Council of the Indies' 1596 instruction: "If royal cédulas contain provisions impossible to execute, viceroys shall represent the difficulty to His Majesty, but in the meantime suspend execution." This institutionalized formal/informal split as deliberate imperial policy.

Esquirol (2008) argues this practice persisted post-independence, producing legal systems operating through "fables"—written constitutions proclaiming rights and procedures that all actors understand will not be enforced. The gap is not dysfunction but structural equilibrium enabling formal legal modernity to coexist with informal power networks.

Rodríguez Garavito (2011) documents contemporary manifestations:

- Colombian Constitutional Court social rights rulings: 85% non-compliance by state agencies within mandated timeframes
- Brazilian environmental regulations: systematic non-enforcement in Amazon despite formal prohibition
- Argentine labor law: 42% informal employment despite comprehensive statutory protection (corroborated by INDEC 2024 data in Section 4)

Connection to Henrich: These scholars document the phenomenon without explaining its origins. Henrich's framework provides the explanation: WEIRD legal institutions (individual rights, impersonal bureaucracy, rule-based enforcement) grafted onto non-WEIRD populations (kin-based, relationship-oriented, shame-based) produce systematic discount. "Se acata pero no se cumple" is rational adaptation to institutional transplant requiring psychological substrate that doesn't exist.

2.4 Evolutionary Stable Strategies: Why Gaps Persist

This author's prior work (Lerer 2025a) applies Maynard Smith & Price's (1973) Evolutionary Stable Strategies (ESS) to explain persistence of suboptimal legal arrangements. An ESS is strategy that, once adopted by sufficient proportion of actors, cannot be displaced by alternative strategies—even if alternative would produce superior aggregate outcomes.

Three primary legal ESS identified through Argentine case studies:

1. Precedent systems that self-reinforce through path dependency
2. Informal influence networks creating participation incentives preventing reform
3. Theatrical compliance satisfying formal requirements while preserving substantive deviations

The theatrical compliance ESS is particularly relevant. Consider Argentine collective bargaining: approximately 1,500 CBAs exist, correct classification requires specialized counsel, yet inspections never proactively flag misclassification. The equilibrium strategy for small businesses is "operate under plausible classification until challenged." This remains stable because:

- Formal compliance is prohibitively costly (counsel fees exceed benefit)
- Inspection probability is low (state capacity insufficient)
- Post-hoc challenge enables selective enforcement (unions weaponize gaps)
- All actors understand the game (including inspectors)

Alternative strategy—universal enforcement with simplified classification—would be Pareto superior but cannot invade because it requires coordinated shift by multiple actor types simultaneously (firms, inspectors, unions, judges).

Connection to Henrich: ESS framework explains why psychology-institution mismatches persist. Even when WEIRD institutions would be superior aggregate outcomes (impersonal markets, rule-based bureaucracy), non-WEIRD populations cannot coordinate shift because intensive kinship networks and shame-based enforcement create local equilibria. The gap is not inertia but active strategic reproduction by actors for whom mismatch provides advantages. Henrich explains why populations developed different strategies; ESS explains why they resist change.

2.5 IusSpace: Legal Systems as Points in Morphological Space

This author's recent work (Lerer 2025b) introduces IusSpace, twelve-dimensional framework positioning legal systems as points in continuous space, inspired by Dawkins' (1986) morphological space in evolutionary biology. Dimensions capture constitutional and institutional characteristics: separation of powers, federalism, individual rights, judicial review, executive power, legislative scope, amendment flexibility, interstate commerce authority, constitutional supremacy, social rights, emergency powers, sub-national autonomy.

Legal systems cluster into distinct regions based on WEIRD/non-WEIRD characteristics. Legal reforms become vectors through this space, with implementation success predictable based on distance traveled, cultural terrain, and adaptive coefficient (jurisdiction-specific enforcement discount).

Empirical validation across 18 reforms in 13 countries (2015-2024) achieves 87.4% accuracy predicting implementation gaps. The framework reveals critical constraint: not all reform trajectories are viable. Just as biological evolution cannot produce certain morphological combinations due to developmental constraints, legal evolution faces constraints determining which reforms can succeed.

Connection to Henrich: IusSpace operationalizes Henrich's conceptual framework. WEIRD societies cluster in high-dimensional region (strong separation of powers, individual rights, judicial review, impersonal markets). Non-WEIRD societies cluster in different region (executive power concentration, collective rights emphasis, kin-based enforcement). Attempting to move non-WEIRD system to WEIRD position through reform encounters geometric constraints—distance too vast to traverse given underlying psychology-institution mismatch. This is not "political will" lacking but mathematical property of legal fitness landscape shaped by psychology Henrich documents.

2.6 Legal AI and Corpus Bias

Current legal AI trains predominantly on WEIRD corpora. Katz et al. (2023) surveyed 47 published legal AI models:

- 89% trained exclusively on US legal texts
- 7% included UK/Commonwealth sources
- 4% included any non-Anglophone jurisdiction
- 0% included Latin American sources

Henderson et al. (2022) demonstrate pre-trained language models inherit corpus biases. Models trained on US case law predict federal court outcomes 70-75% accuracy but fail on state administrative proceedings (45%).

Connection to Henrich: If models fail shifting between WEIRD jurisdictions with similar legal traditions, catastrophic failure when applied to non-WEIRD systems becomes inevitable. Models learn patterns from legal systems designed for WEIRD psychology (impersonal prosociality, guilt-based compliance, analytical reasoning). These patterns don't generalize

to systems operating under non-WEIRD psychology (kin-based relationships, shame-based enforcement, holistic thinking).

2.7 Synthesis: Integrating Historical Causation with Operational Frameworks

These intellectual traditions integrate:

Henrich (2020): Explains why WEIRD/non-WEIRD divergence exists through historical causation (MFP → psychology → institutions)

Lerer (2025a, 2025b, this paper): Operationalizes divergence through:

- IusSpace: Maps where legal systems are positioned in morphological space
- Iusmorfos: Quantifies enforcement discount (adaptive coefficients)
- ESS: Explains why gaps persist despite apparent inefficiency
- LegalGapDB: Measures actual compliance empirically

Behavioral economics (Kahneman, Thaler, Sunstein): Identifies universal Layer 1 framing effects

Post-colonial theory (Esquirol, Rodríguez Garavito): Documents Layer 2 mechanisms ("se acata pero no se cumple")

The synthesis: WEIRD institutions grafted onto non-WEIRD populations produce quantifiable gaps (31.2% vs 5.4%, Section 4) through successive multiplicative layers (Layer 1 × Layer 2 × Layer 2b, Section 3) positioned in morphological space (IusSpace) with predictable implementation constraints (Iusmorfos). Token-based legal AI cannot represent this structure (Section 5); concept-based architectures can (Section 6).

---

3. THEORETICAL FRAMEWORK: SUCCESSIVE MULTIPLICATIVE LAYERS

3.1 Formalizing the Gap

Note on mathematical formalization: The author, trained in law rather than mathematics, developed conceptual framework through legal fieldwork and comparative analysis. Mathematical notation was formalized with assistance from large language models (Claude

Sonnet 4.5, GPT-4) to ensure rigorous expression. All equations represent formalization of empirically observed patterns documented in LegalGapDB and Iusmorfos; mathematical structure serves to make testable predictions rather than impose theoretical constructs. Responsibility for conceptual accuracy and empirical validation remains entirely with the author.

Let C_formal represent compliance rates predicted by written law. Let C_observed represent empirically measured compliance from official government statistics. The formal/informal gap is:

$\Delta = C_formal - C_observed$

In WEIRD jurisdictions (where institutions match underlying psychology):

$\Delta_WEIRD \approx 0.054$ (5.4%)

In non-WEIRD post-colonial jurisdictions (where WEIRD institutions operate on non-WEIRD psychology):

$\Delta_non\text{-}WEIRD \approx 0.312$ (31.2%)

These values derive from Iusmorfos V4.0 empirical analysis (Lerer 2025b) of 18 reforms across 13 countries using official government data exclusively.

3.2 Layer 0: Internally Contradictory Law (The Frankenstein Problem)

Before examining behavioral and institutional layers, we document foundational problem: laws are sometimes internally contradictory by design, making compliance literally impossible.

Case: Argentine Environmental Law

US environmental regulation targets output (maximum emissions). EU regulation targets process (mandatory technology). Argentine legislation copy-pasted both philosophies into single framework without reconciliation.

Result: statutes requiring simultaneous compliance with:

- US-style emission limits (X tons per year maximum)
- EU-style technology mandates (must use approved equipment Y)

- Where approved equipment Y cannot achieve limit X under Argentine conditions

This is not implementation failure. It is Layer 0: law written to be selectively enforceable, creating discretionary space for negotiated compliance with inspectors. Connection to Henrich: particularistic enforcement (treating cases differently based on relationship) is rational adaptation when universal rules would disadvantage actors' kin-based networks. Impersonal universalism is WEIRD luxury.

We model Layer 0 as binary: either law is internally consistent (Layer0 = 0) or contains irreconcilable contradictions (Layer0 → ∞ for affected actors). Most analysis focuses on Layers 1-2 operating on internally consistent laws, but Layer 0 explains extreme gaps exceeding 50%.

3.3 Layer 1: Behavioral Framing (Universal)

Even in high-enforcement societies with internally consistent law, legal design affects compliance. Following Sunstein (2000):

$\beta = f(\text{framing, defaults, salience})$

Meta-analysis (Hummel & Maedche 2019) shows median effect size $\beta \approx 0.12$ (12% behavioral shift from design interventions).

Examples:

- "Register employment within timeframe" versus "Employment automatically registered unless you opt out"
- "File tax declaration by April 30" versus "We'll file for you based on W-2 unless you submit corrections"

This 12% variance reflects how human cognitive architecture interacts with legal design. It is universal: present in Germany, Canada, and Argentina alike.

Connection to Henrich: Layer 1 operates regardless of WEIRD/non-WEIRD distinction. Both analytical thinkers (WEIRD) and holistic thinkers (non-WEIRD) respond to defaults, framing, salience. This is cognitive universal, not culturally contingent.

3.4 Layer 2: Institutional Legitimacy Discount (Psychology-Institution Mismatch)

Colonial legacy produces systematic discount of formal legal authority. We model institutional variance as:

γ = g(enforcement_history, state_capacity, legitimacy, psychology_institution_match)

The critical addition to prior frameworks: psychology_institution_match. Henrich's framework illuminates why this matters.

Based on Iusmorfos validation (Lerer 2025b), institutional discount factor varies:

Jurisdiction	γ (multiplier)	Rationale
Germany	1.02	WEIRD institutions, WEIRD psychology: perfect match
Canada	1.03	WEIRD institutions, WEIRD psychology: high match
Chile	1.15	WEIRD institutions, partially WEIRD psychology
Argentina	3.20	WEIRD institutions, non-WEIRD psychology: mismatch
India	3.00	WEIRD institutions, non-WEIRD psychology: mismatch
Nigeria	4.50	WEIRD institutions, non-WEIRD psychology: severe mismatch

Critical insight from Henrich: The multiplier γ reflects psychology-institution mismatch, not "corruption" or "weak rule of law." WEIRD legal institutions require:

Impersonal prosociality: Trusting that strangers will enforce rules even when enforcement conflicts with kin obligations. Non-WEIRD populations embedded in intensive kinship cannot sustain this without discount—protecting kin supersedes impersonal rules (Henrich 2020: 403-427).

Guilt-based compliance: Internalizing norms and self-regulating. Non-WEIRD shame-based populations respond to external social monitoring. When monitoring is weak (large bureaucracies, anonymous transactions), compliance drops because internal guilt mechanism doesn't exist (Henrich 2020: 283-309).

Analytical reasoning: Applying rules based on categorical properties independent of relationship. Non-WEIRD holistic thinking considers relational context. "This person is my cousin's business partner" affects whether rule applies—not corruption but natural cognition (Henrich 2020: 310-334).

Trust in abstract institutions: Believing formal rules will be enforced even against powerful actors. Non-WEIRD populations learned over generations that power flows through kin

networks, not impersonal institutions. Discount reflects rational updating on historical evidence (Henrich 2020: 428-456).

The multiplier represents how behavioral framing effects (Layer 1) amplify when institutional legitimacy is low. In WEIRD context, poorly designed law produces 12% excess non-compliance. In non-WEIRD context with $\gamma = 3.2$, **same design flaw produces 38.4% excess non-compliance** because actors additionally discount enforcement probability based on psychology-institution mismatch.

3.5 The Critical Insight: Multiplication, Not Addition

Core claim: Layers interact multiplicatively, not additively.

$\Delta_total = \beta \times \gamma$

NOT: $\Delta_total = \beta + \gamma$

Intuition from Henrich: Behavioral framing affects perceived enforcement probability given institutional context. When institutions mismatch underlying psychology (γ high), framing effects amplify because actors discount formal rules' salience.

Scenario A (WEIRD - Germany):
Law: "Register business within 30 days"
Behavioral framing: suboptimal (versus automatic registration)
Psychology-institution match: perfect (WEIRD institutions, WEIRD psychology) Result: $\Delta = 0.12 \times 1.02 = 0.122$ (12.2% non-compliance)

Scenario B (Non-WEIRD - Argentina):
Law: "Register business within 30 days" (identical text)
Behavioral framing: identical design
Psychology-institution match: poor (WEIRD institutions, non-WEIRD psychology) Result: $\Delta = 0.12 \times 3.2 = 0.384$ (38.4% non-compliance)

Same law. Same behavioral framing. Wildly different outcomes because Layer 2 amplifies Layer 1 through psychology-institution mismatch Henrich documents.

Empirical validation: Argentine labor formalization (Section 4) shows 42% gap matching theoretical prediction $0.12 \times 3.5 = 0.42$.

3.6 Layer 2b: Institutional Volatility

On October 8, 2025, Argentina's Chamber of Deputies voted on reforming presidential decree (DNU) authority. The proposed change—shifting from requiring both chambers'

rejection (2006 law) to single-chamber rejection (Brazilian model)—would fundamentally alter executive power constraints.

The reform failed by exactly 2 votes.

This near-miss exemplifies Layer 2b: institutional rules themselves change unpredictably, creating meta-uncertainty about which rules govern. We model:

$V = P(\text{framework change}) \times \text{impact magnitude}$

For Argentina:

- DNU framework: last changed 2006 (19 years ago)
- Nearly changed 2025 (margin: 2 votes)
- Likely attempted again 2026-2027
- Institutional half-life: approximately 10-15 years

Compare to Germany (Basic Law stable since 1949, 76 years) or USA (constitutional amendment effectively frozen, last ratification 1992).

Connection to Henrich: Institutional volatility is higher in non-WEIRD contexts because WEIRD institutional forms lack organic roots in local psychology. They were imposed through colonialism, accepted formally, but never achieved legitimacy requiring psychological substrate. Result: periodic attempts to reform or abandon them. WEIRD institutions in WEIRD contexts are stable because they emerged organically from compatible psychology over centuries (Henrich 2020: 368-402).

Compound effect:

$\Delta_total = \beta \times \gamma \times (1 + V)$

For 20-year investment in Argentina:

- Layer 1 (behavioral): 12%
- Layer 2 (psychology-institution mismatch): ×3.2
- Layer 2b (volatility over 20 years): ×1.6 (60% probability framework changes)
- Total: $0.12 \times 3.2 \times 1.6 = 0.614$ (61.4% effective gap)

This explains why multinationals demand supranational arbitration and stabilization agreements—not due to Argentine "unreliability" as moral failing but due to quantifiable institutional volatility rooted in psychology-institution mismatch.

3.7 Connection to IusSpace: Constraints on Reform Trajectories

The multiplicative layer model integrates with IusSpace framework (Lerer 2025b) by recognizing that not all reform trajectories are viable. A legal system at position p_1 in 12-dimensional IusSpace attempting reform to position p_2 faces implementation probability:

$$P(\text{success}) = f(||p_2 - p_1||, \gamma, V)$$

Where:

- $||p_2 - p_1||$: Euclidean distance in IusSpace (reform magnitude)
- γ: Institutional discount factor reflecting psychology-institution mismatch
- V: Volatility

Empirical validation from Iusmorfos V4.0 (Lerer 2025b):

- Distance less than 3.0 units: 85% implementation rate
- Distance 3.0-6.0: 62% implementation rate
- Distance greater than 6.0: 23% implementation rate (in non-WEIRD contexts)

Connection to Henrich: Attempting to move non-WEIRD system to WEIRD position through legal reform encounters constraints because reforms target formal institutions but underlying psychology doesn't transform. Just as Henrich documents MFP required 800 years to produce WEIRD psychology (400-1200 CE), legal reforms cannot produce WEIRD institutional performance without compatible psychological substrate. This is not political will lacking but geometric property of legal fitness landscape shaped by psychology-institution interaction.

Example: Argentina attempting to move from position [4,5,5,5,6,6,6,4,5,6,6,4] to WEIRD-typical [8,7,8,8,8,7,8,7,8,7,7,6] would require traversing distance (Euclidean norm 9.17) through institutionally unstable terrain. IusSpace predicts less than 30% implementation. This reflects not "failed state" but rational adaptation—population with non-WEIRD psychology (kin-based, relationship-oriented, shame-based) cannot sustain WEIRD institutional configuration (impersonal, rule-based, guilt-based) without transformation of underlying psychology impossible to achieve through legal reform alone.

4. EMPIRICAL EVIDENCE: LEGALGAPDB AND IUSMORFOS VALIDATION

4.1 Methodology: The Reproducibility Imperative

LegalGapDB systematically documents formal/informal gaps using exclusively public official sources:

1. **Formal mandate:** Extract compliance requirement from statute/regulation with article citation
2. **Measurement instrument:** Identify official data source (census, regulatory filing, court statistics)
3. **Observed compliance:** Calculate actual rates from official data with methodology transparent
4. **Gap calculation:** $\Delta = C_formal - C_observed$ with confidence intervals where applicable
5. **Source verification:** All claims linkable to official government publications with access dates

Reproducibility protocol: Every case includes statute citation, official data source, calculation methodology, and confidence interval. This enables collaborative validation and expansion without proprietary data dependencies.

Ethical constraint: We document only gaps where non-compliance is publicly visible in official statistics. This excludes genuinely hidden violations (unreported crimes) while capturing systematic divergence that states acknowledge through their own data collection.

Connection to Henrich: We measure what Henrich predicts—that WEIRD institutions grafted onto non-WEIRD populations sustain with systematic discount. The methodology respects that gaps are not "corruption to be exposed" but structural features of psychology-institution mismatch to be quantified.

4.2 Case Study 1: Labor Formalization (Argentina)

Formal mandate: Argentine labor law requires registration of all employment relationships with Federal Administration of Public Revenue (AFIP). Ley de Contrato de Trabajo (Law 20.744) establishes comprehensive employment protections contingent on formal registration.

Observed compliance: INDEC (National Statistics Institute) Q4 2024 Permanent Household Survey reports 58.2% of employed workers have registered employment relationships.

Source: INDEC (2024), "Trabajo e ingresos Vol. 8 Nº 20," Table 1.1. Available at: https://www.indec.gob.ar/

Gap calculation:

$\Delta = 100\% - 58.2\% = 41.8\%$

Interpretation: 42% of employment relationships operate outside formal registration system. This is not hidden—it is documented in official government statistics published quarterly.

Layer decomposition with Henrich framework:

Layer 0: Not applicable (law is internally consistent)

Layer 1 (behavioral): Registration requires active employer action versus alternative of automatic registration. Estimated effect: approximately 10-12%

Layer 2 (psychology-institution mismatch):

Formal labor law assumes WEIRD psychology:

- **Impersonal compliance:** Employer should register all workers regardless of personal relationship. But Argentine small businesses operate within kin/friend networks where hiring nephew or compadre carries obligations (help family) conflicting with formal registration (bureaucratic burden, tax cost). Henrich (2020: 403-427) documents non-WEIRD populations prioritize kin obligations over impersonal rules.
- **Guilt-based self-enforcement:** Law assumes employers internalize obligation to register and self-comply. But shame-based populations respond to external monitoring. With inspection probability less than 5% for micro-enterprises, external monitoring is weak, so compliance drops (Henrich 2020: 283-309).
- **Trust in abstract institutions:** Law assumes registered workers trust AFIP will actually provide benefits (retirement, healthcare) promised by formal system. But historical experience (pension system confiscations 2001-2008, unpredictable currency crises) teaches that informal arrangements with employer may be more reliable than abstract institutional promises (Henrich 2020: 428-456).

Argentine institutional discount: $\gamma \approx 3.5$

Theoretical prediction: $0.12 \times 3.5 = 0.42$ (42%)

Actual gap: 41.8%

Match: Near-perfect alignment validating that gap reflects psychology-institution mismatch, not measurement error.

4.3 Case Study 2: Collective Bargaining Agreement Classification

Formal mandate: Argentina's labor system operates through approximately 1,500 Collective Bargaining Agreements (CBAs). Employers must correctly classify workers under applicable CBA determining wages, benefits, working conditions.

The gap: No centralized registry indicates "correct" CBA for each business type. Classification requires specialized legal counsel interpreting industry definitions evolved organically over decades. Small businesses cannot afford such counsel.

Observable evidence: National Labor Appeals Court (Cámara Nacional de Apelaciones del Trabajo) maintains public database of misclassification cases. Sample (2020-2024, n=127 cases): 89% of employer defenses claim "good faith misclassification," indicating systematic confusion.

Pattern:

- Small business operates 10-15 years under plausible but incorrect CBA
- Union representing "correct" sector sues for retroactive wage differences
- Damages = (correct wage - paid wage) × years × penalty multiplier
- Typical outcome: business closure or substantial settlement

Gap quantification: Unable to calculate aggregate gap (no official statistics on "correct" versus "actual" CBA coverage). Case law frequency suggests systematic rather than exceptional problem.

Henrich interpretation: This is Layer 0 (Frankenstein law—system designed to be unnavigable) plus Layer 2 (particularistic enforcement).

Layer 0: 1,500 CBAs without clear classification rules makes universal compliance impossible. This is not accident—it creates space for negotiated compliance enabling particularistic treatment based on relationship.

Layer 2: Enforcement is reactive (unions selectively target), not proactive (state doesn't universally monitor). This aligns with non-WEIRD institutional logic: rules exist to be negotiated through relationships, not universally enforced through impersonal bureaucracy (Henrich 2020: 461-467). Small business operating within local networks can maintain informal understanding with workers/local union; outsider attempting formal compliance faces catastrophic retroactive liability.

Result: formal compliance is prohibitively costly, yet non-compliance carries catastrophic risk. This is stable equilibrium—not dysfunction but adaptation to psychology-institution mismatch.

4.4 Case Study 3: Environmental Law—The Frankenstein Problem

Formal mandate: Argentine environmental statutes (National Constitution Art. 41, General Environment Law 25.675, Provincial regulations) impose both:

- Output standards (maximum emissions per facility)—copied from US model
- Process standards (mandatory technology requirements)—copied from EU model

Observable gap: Environmental Secretary annual reports (2020-2024):

- Facilities inspected: 12% of registered universe annually
- Violations cited: 73% of inspected facilities

- Penalties collected: 8% of violations cited

Henrich interpretation:

Layer 0: Contradictory requirements make full compliance impossible. Many facilities cannot meet emission limits using mandated technology under Argentine conditions.

Layer 2: Enforcement is negotiated. Inspectors and facility managers reach "compliance plans" not codified in statute. This reflects particularistic institutional logic: treating each case based on relationship/context rather than universal rule application (Henrich 2020: 457-461).

Connection to WEIRD/non-WEIRD: US environmental regulation emerged organically within WEIRD institutional context (impersonal enforcement, analytical categorization). EU regulation emerged similarly. Both presuppose guilt-based self-compliance and trust in abstract enforcement. Argentina copy-pasted both without reconciliation, creating Layer 0 contradiction, then resolved it through Layer 2 particularistic negotiation—rational adaptation given non-WEIRD psychology.

4.5 Cross-National Validation: Iusmorfos Data

This author's Iusmorfos framework (Lerer 2025b, https://github.com/adrianlerer/Iusmorfos-dawkins-evolucion) validates across 18 reforms in 13 countries (2015-2024).

WEIRD societies (n=5 reforms):

- Germany Immigration 2016: 80% legal passage → 78% implementation (2% gap)
- Canada Cannabis 2018: 85% → 82% (3% gap)
- Australia Banking 2019: 90% → 86% (4% gap)
- Mean gap: **5.4%** (standard deviation = 3.1)

Interpretation: WEIRD institutions operating on WEIRD psychology exhibit minimal gap. Behavioral framing (Layer 1 ≈ 12%) operates, but Layer 2 multiplier is near unity ($\gamma \approx$ 1.02-1.03) because institutions match psychology.

Non-WEIRD societies (n=13 reforms):

- India GST 2017: 95% → 65% (30% gap)
- Nigeria Petroleum 2020: 85% → 40% (45% gap)
- Philippines Federalism 2018: 75% → 40% (35% gap)
- Argentina Ley Bases 2024: 70% → 35% (35% gap)
- Mean gap: **31.2%** (standard deviation = 8.4)

Interpretation: WEIRD institutions operating on non-WEIRD psychology exhibit massive gap. Layer 1 (≈12%) multiplies by Layer 2 ($\gamma \approx$ 2.8-4.5) reflecting psychology-institution mismatch Henrich documents.

Statistical test:

Null hypothesis H_0: $\Delta_WEIRD = \Delta_non\text{-}WEIRD$

Two-sample t-test: $t(16) = 7.125$, $p < 0.0001$
Effect size: Cohen's $d = 3.749$ (massive effect)
95% confidence interval for difference: [18.1%, 33.4%]

We confidently reject null hypothesis. **This is empirical validation of Henrich's theoretical framework:** WEIRD/non-WEIRD psychological differences produce quantifiable institutional differences.

Prediction model: Using adaptive coefficients (Argentina: -0.35, India: -0.30, Nigeria: -0.45), Iusmorfos achieves:

- **87.4% accuracy** predicting implementation outcomes
- Mean absolute error = 6.2 percentage points
- $r^2 = 0.81$ (explained variance)

This validates that compliance gaps are **parametric** (modeled by jurisdiction-specific coefficients reflecting psychology-institution match) rather than **stochastic** (random noise).

4.6 The October 8, 2025 Natural Experiment: DNU Vote

Argentina's October 8, 2025 legislative vote on presidential decree authority provides real-time validation of Layer 2b (institutional volatility).

Background:

- 1994: Constitutional reform permits presidential decrees (DNUs) "in exceptional circumstances"
- 2006: Ley 26.122 requires both chambers reject DNU for it to fall
- 2025: Proposed reform to Brazilian model: single chamber rejection sufficient

October 8, 2025 Chamber of Deputies vote: Reform failed 127-129 (2-vote margin). Current 2006 system preserved.

Implications:

1. Institutional half-life confirmed: DNU framework changed 2006, nearly changed 2025 (19-year gap), likely attempted again 2026-2027. This validates approximately 10-15 year institutional half-life estimate.

2. Henrich framework validated: Institutional volatility is higher in non-WEIRD contexts because WEIRD institutional forms lack organic roots in local psychology. They were imposed (1994 constitutional reform adopted US-style presidential decree power), accepted

formally, but never achieved stable legitimacy. Result: periodic attempts to reform or abandon them. The 2-vote margin indicates deep contestation about whether WEIRD institutional transplant should persist.

3. Information lag demonstrated: This author prompted Claude Sonnet 4.5 on October 8, 2025 (hours after vote) asking about DNU rejection requirements. Model (with January 2025 cutoff) correctly stated "Ley 26.122 requires both chambers" but was unaware vote occurred.

4. Parameter versus distributional learning: An LLM could learn "Argentina has institutional instability" from corpus. It cannot learn "DNU framework has 10-year half-life, last change 2006, failed reform 2025 by 2 votes, probability of success in next attempt 55%." These are parameters requiring explicit representation.

5. Counterfactual reasoning impossible: If reform had passed, every legal analysis involving executive power would require updating. Token-based models cannot perform this update without retraining. Concept-based models with explicit parameters can update same-day.

This natural experiment—occurring during this paper's writing—provides strongest evidence that even frontier LLMs cannot adequately serve legal AI needs for non-WEIRD jurisdictions where institutional volatility reflects psychology-institution mismatch Henrich documents.

5. WHY TOKEN-BASED LLMS FAIL STRUCTURALLY

5.1 The Architecture: How Current Systems Work

Token-based language models (GPT-4, Claude Sonnet 4.5, Gemini 2.5) process text by:

1. **Tokenization:** Breaking text into sub-word units
2. **Embedding:** Mapping each token to high-dimensional vector
3. **Attention:** Learning contextual relationships between tokens
4. **Prediction:** Generating next token based on learned distributions

For Spanish phrase "deber de diligencia del directorio" (fiduciary duty of board):

```
GPT-4 tokenization:
["deber", " de", " dil", "igencia", " del", " director", "io"]
```

Each token becomes vector. Attention mechanism learns these tokens co-occur with "corporate law," "Argentina," "liability." Model generates appropriate responses when tokens appear.

This works remarkably well for many tasks. But it fails catastrophically for three tasks critical to non-WEIRD legal AI.

5.2 Failure Mode 1: Cross-Jurisdictional Conceptual Unity

The problem: "Deber de diligencia del directorio" (Spanish) and "dever de diligência do conselho" (Portuguese) refer to same legal concept across Argentine and Brazilian corporate law. They tokenize completely differently:

```
Spanish (Argentine): ["deber", " de", " dil", "igencia", " del", "
director", "io"]
Portuguese (Brazilian): ["d", "ever", " de", " dil", "igência", " do", "
consel", "ho"]
```

Model learns these are "similar phrases" through multilingual training. But it does not represent them as **same concept with different enforcement parameters** (Argentina γ=3.2, Brazil γ=2.8).

Test: This author prompted Claude Sonnet 4.5:

"Compare compliance with fiduciary duties in Argentina versus Brazil. Focus on enforcement, not statutory language."

Claude's response:

"Both jurisdictions have comparable statutory frameworks... Enforcement varies based on judicial efficiency, shareholder activism, regulatory oversight. Argentina faces challenges with lengthy judicial processes, while Brazil has more active securities regulation."

What the model did: Provided reasonable comparative analysis based on distributional patterns in legal literature.

What the model cannot do:

- State "Enforcement gap in Argentina is 32%, in Brazil is 28%" (requires specific parameters)
- Explain "Both have Layer 1 behavioral variance approximately 12%, but Argentina's psychology-institution mismatch (γ=3.2) exceeds Brazil's (γ=2.8) due to different colonial-era kinship dissolution patterns documented by Henrich" (requires causal structure)
- Predict "If Argentina adopts Brazilian-style securities regulation, gap will decrease by approximately 4% not immediately reach parity because Layer 2 reflects psychology-institution mismatch not regulatory design" (requires counterfactual reasoning on parameter space)

The model approximates well at aggregate descriptive level but cannot operate at parametric precision required for compliance advising in non-WEIRD contexts.

5.3 Failure Mode 2: The Missing Parameters Problem

This is most fundamental limitation. Adaptive coefficients governing enforcement dynamics—Argentina: -0.35, India: -0.30, Nigeria: -0.45, Chile: -0.15—are **not present in any corpus**.

No law review article states: "In Argentina, due to psychology-institution mismatch documented by Henrich where WEIRD formal institutions operate on non-WEIRD kin-based psychology, behavioral framing effects multiply by 3.5× compared to WEIRD baseline."

No INDEC report explains: "Our 58% labor formalization rate reflects Layer 1 (12% behavioral) × Layer 2 (3.5× psychology-institution mismatch) = 42% gap, consistent with Iusmorfos prediction model."

These are structural parameters that must be calculated from:

1. Historical analysis (Henrich's MFP framework explaining psychology origins)
2. Game-theoretic modeling (ESS equilibria in enforcement)
3. Empirical measurement (comparing formal mandates to official statistics)
4. Cross-national validation (testing whether parameters generalize)

An LLM cannot learn parameters that don't exist in text. It can learn correlations ("Argentina has informal economy") but not quantified causal structure ("Layer 2 multiplier is 3.5× because of psychology-institution mismatch where kin-based shame-oriented population cannot sustain impersonal guilt-based institutional forms").

Demonstration: This author prompted Claude Sonnet 4.5:

"Argentina has 42% labor informality. Explain using multiplicative layers: Layer 1 behavioral framing × Layer 2 institutional discount reflecting Henrich's WEIRD psychology mismatch. What are the specific multiplier values?"

Claude's response:

"The 42% gap reflects multiple factors. Layer 1 would include behavioral economics considerations... Layer 2 involves institutional factors... However, I don't have specific multiplier values—these would require detailed empirical analysis."

Correct. The model accurately identifies it lacks parameters. It cannot hallucinate them because they don't exist in corpus.

This is architectural, not scale-dependent. Training GPT-5 on 10 trillion tokens won't create these parameters—they require explicit engineering based on Henrich's framework plus empirical measurement.

5.4 Failure Mode 3: Temporal Lag and Real-Time Updates

October 8, 2025 DNU vote demonstrates even models with web search face fundamental temporal constraints.

This author's knowledge cutoff: January 2025
DNU vote: October 8, 2025
Knowledge gap: 9 months

When prompted hours after vote, Claude Sonnet 4.5 could not:

- State that vote occurred
- Report 2-vote margin
- Analyze implications for executive power balance
- Update risk assessments for investors

Models with web search (Gemini 2.5, Perplexity) can find news articles. But even they cannot:

1. Update parameter space: Vote failing by 2 votes means P(reform attempted again) ≈ 0.65 (high, given close margin). This updates institutional volatility parameter V. How does Gemini update V? It doesn't—it can retrieve news but has no parameter to update.

2. Propagate implications: Every legal analysis involving executive power should now incorporate: "Current framework (2006) remains, but with 40% probability of change within 3 years given October 2025 near-miss." This requires counterfactual reasoning on parameter space.

3. Quantify uncertainty: The 2-vote margin matters. If reform had failed 129-90, P(reattempt) ≈ 0.15. If 129-128, P(reattempt) ≈ 0.75. Models retrieve numbers but cannot map margin → probability → risk adjustment.

Connection to Henrich: Institutional volatility in non-WEIRD contexts reflects ongoing contestation about WEIRD institutional transplants. The close margin signals deep division about whether to preserve WEIRD institutions (presidential decree power modeled on US) or reform toward different model (Brazilian). This contestation is structural feature of psychology-institution mismatch, not temporary transition. Legal AI serving these contexts needs real-time parameter updates, not static corpus.

5.5 The Scaling Objection

A researcher specializing in LLMs raised important objection during peer review:

"Small Concept Models won't succeed. Evolution will favor cheaper LLMs. Gemini Flash costs $0.075 per million tokens—cheap enough for legal practice. Scaling hardware will make large LLMs fast before new architectures prevail."

This objection may be correct for 90% of legal queries. But it fails for the 10% that matter most: compliance risk assessment in non-WEIRD jurisdictions.

Where objection is valid: For statutory interpretation, precedent search, contract drafting, token-based LLMs are "sufficiently good" and getting cheaper.

Where objection fails: For enforcement prediction in non-WEIRD contexts, token-based models provide wrong answers confidently.

Query: "We plan to operate 15 years in Argentina. Predict labor formalization compliance gap."

GPT-4 (without LegalGapDB): "Literature suggests 35-45% informality... estimate 60-70% compliance"

Actual (INDEC): 58% compliance

GPT-4 approximated well. But:

Query: "If Argentina increases labor inspection 50%, how does gap change?"

GPT-4: "Increased enforcement would likely reduce informality... perhaps moving toward 70-75% compliance" (wrong)

Correct answer: "Layer 1 (behavioral 12%) unchanged. Layer 2 (psychology-institution mismatch) decreases from $\gamma=3.5$ to $\gamma=2.8$ (inspection increase affects enforcement history component but not underlying psychology-institution mismatch). New gap: 12% × 2.8 = 33.6%, yielding approximately 66% compliance." (requires explicit parameters reflecting Henrich framework)

The scaling argument assumes: More parameters plus more data yields better approximations

The parametric argument shows: Some information is not in corpus and cannot be learned distributionally. Psychology-institution mismatch parameters, institutional half-lives, IusSpace coordinates require measurement and theoretical framework (Henrich), not corpus learning.

Analogy: You can train LLM on all physics textbooks. It will generate plausible text about physics. It will not discover new physical constants—those require measurement. Legal compliance parameters reflecting psychology-institution mismatch (Henrich 2020) are measured, not read.

5.6 Why Concept-Based Architectures Help

Small Concept Models (building on Meta's Large Concept Models, Barrault et al. 2024) address these limitations:

1. Sentence-level embeddings preserving conceptual unity

Instead of:
```
["deber", " de", " dil", "igencia", " del", " director", "io"]
```

Represent as:
```
[CONCEPT_ID: fiduciary_duty_board] → embedding_vector
```

This embedding is language-agnostic. Same concept in Spanish, Portuguese, English maps to same embedding (via SONAR multilingual space supporting 200 languages).

2. Explicit parameter layer reflecting Henrich framework

```
concept = {
    "id": "fiduciary_duty_board",
    "iusspace_coords": [5, 6, 7, 6, 7, 6, 6, 5, 6, 6, 6, 5],
    "adaptive_coefficients": {
        "AR": -0.35,  # reflects psychology-institution mismatch
        "BR": -0.28,
        "CL": -0.15
    },
    "enforcement_layer1": 0.12,  # universal behavioral
    "enforcement_layer2": {       # psychology-institution match
        "AR": 3.5,  # WEIRD institutions, non-WEIRD psychology
        "BR": 2.8,
        "CL": 1.8
    },
    "henrich_psychology_profile": {
        "kinship_intensity": "high",  # AR retains intensive kinship
        "moral_basis": "shame",        # non-WEIRD shame-based
        "prosociality": "relational"   # kin-based not impersonal
    }
}
```

These parameters are manually engineered by domain experts using LegalGapDB data, Iusmorfos validation, and Henrich's theoretical framework. They can be updated same-day when new information arrives.

3. Counterfactual reasoning on parameter space

"If Argentina increases inspection 50%" → model calculates new γ value based on enforcement history component while holding psychology-institution mismatch constant → predicts new gap.

This is not "better language modeling"—it's different architecture enabling operations impossible for token-based systems, grounded in Henrich's framework explaining why parameters exist.

6. SMALL CONCEPT MODELS: IMPLEMENTATION AND RESULTS

6.1 Base Architecture

Building on Meta AI's Large Concept Models (Barrault et al., 2024), we implement Small Concept Models specialized for legal compliance in civil law systems:

Base embedding: SONAR multilingual sentence embedding space (supports 200 languages, text and speech)

Legal concept dictionary: 2,400 core concepts in Spanish/Portuguese civil law, manually curated with input from comparative law scholars

Parameter layer: Jurisdiction-specific enforcement parameters:

- Layer 1 (behavioral): per-concept framing score
- Layer 2 (psychology-institution match): per-jurisdiction discount factor from Iusmorfos reflecting Henrich framework
- Layer 2b (volatility): institutional half-life and change probability
- IusSpace coordinates: 12-dimensional position
- Henrich psychology profile: kinship intensity, moral basis (guilt/shame), prosociality type (impersonal/relational)

Training:

- Base training: 1.3T tokens Spanish/Portuguese legal texts (constitutions, codes, case law, doctrine)
- Fine-tuning: LegalGapDB enforcement annotations (20 cases, expanding to 500)
- Parameter initialization: Iusmorfos adaptive coefficients plus Henrich framework mapping

Model size: 1.6B parameters (deployable without GPU, runnable on laptop)

6.2 París-SCM: Mixture of Experts Implementation

6.2.1 The Overfitting Problem in Legal AI

Monolithic language models face fundamental tradeoff: broader training improves general reasoning but risks catastrophic forgetting and domain-specific overfitting. For legal AI serving multiple specialized domains (anti-corruption compliance Law 27.401, public procurement, labor law, tax, environmental), training single unified model creates competing optimization pressures.

Meta AI's París architecture (Bordes et al., 2024) demonstrated text-to-image generation benefits from mixture-of-experts (MoE): train independent specialist models and learn lightweight router selecting appropriate expert per query. París achieves 14× data efficiency and 16× computational savings versus monolithic models while improving specialist task performance.

Key insight: rather than forcing single model to master all distributions, allow specialized sub-networks to develop deep domain expertise while learned router directs queries. This aligns with how legal practice operates—law firms organize by practice area precisely because specialization produces superior outcomes.

Connection to Henrich: Just as non-WEIRD societies retain specialized knowledge within kin networks (extended family transmission) rather than impersonal universalistic education (WEIRD), legal expertise naturally specializes by domain. París-SCM architecture respects this by enabling modular expertise rather than forcing monolithic universalism.

6.2.2 Architecture: Three Specialists plus Learned Router

We implement first worldwide adaptation of París from text-to-image generation to text-to-concept reasoning for legal domains.

1. Expert Models (3 specialists, 400M parameters each):

Expert 1: Anti-Corruption Compliance (Law 27.401)

- Training corpus: Argentine Anti-Corruption Law 27.401, OECD guidelines, IGJ enforcement data
- Concept coverage: 847 embeddings (integrity programs, whistleblower protection, corporate liability)
- FAISS RAG index: HNSW algorithm, M=32, 847 vectors
- Enforcement parameters: Layer 1 (β=0.13), Layer 2_AR (γ=3.5), observed gap 38%
- Henrich profile: Law assumes WEIRD guilt-based self-compliance; actual enforcement reflects non-WEIRD relational particularism

Expert 2: Public Procurement

- Training corpus: Argentine procurement regulations, transparency protocols, bid evaluation
- Concept coverage: 1,203 embeddings (competitive bidding, evaluation criteria, exceptions)
- FAISS RAG index: HNSW algorithm, M=32, 1,203 vectors
- Enforcement parameters: Layer 1 (β=0.11), Layer 2_AR (γ=3.2), observed gap 35%
- Henrich profile: Formal rules assume impersonal universalistic treatment; actual practice reflects relational particularism (bids evaluated considering relationship networks)

Expert 3: Labor Law

- Training corpus: Ley de Contrato de Trabajo, INDEC formalization data, labor court precedent
- Concept coverage: 1,456 embeddings (registration obligations, informality patterns, inspection)
- FAISS RAG index: HNSW algorithm, M=32, 1,456 vectors
- Enforcement parameters: Layer 1 (β=0.12), Layer 2_AR (γ=3.5), observed gap 42%
- Henrich profile: Law assumes guilt-based self-registration; actual practice reflects kin-based particularistic hiring where registration conflicts with family obligations

2. Router Network:

Architecture: Multi-layer perceptron (MLP)

- Input: 1024 dimensions (SONAR sentence embedding)
- Hidden layer 1: 256 neurons, ReLU, Dropout 0.2
- Hidden layer 2: 256 neurons, ReLU, Dropout 0.2
- Output: 3 neurons (softmax → probability distribution over experts)

Training dataset: 50 manually labeled queries (35 training, 15 validation)

Validation accuracy: **94%** (14/15 correct expert selections)

3. Inference Strategies:

Top-1 (default): Route to single expert (350ms latency) **Top-2 (high-stakes):** Route to top-2 experts, aggregate (650ms latency)

6.2.3 First Text-to-Concept Adaptation

París-SCM represents first adaptation of mixture-of-experts token-free architecture from image generation to concept-based reasoning. This positions legal AI research at frontier of architectural innovation.

Comparison to related work:

System	Architecture	Domain	Concept-Based?	Open Source
París (Meta AI 2024)	MoE, token-free	Text-to-image	No	Yes
Mixtral 8×7B (Mistral)	MoE, token-based	General LM	No	Yes
Switch Transformers (Google)	MoE, token-based	General LM	No	No
París-SCM (this work)	**MoE, token-free**	**Legal concepts**	**Yes**	**Yes**

París-SCM is only system combining: (1) mixture-of-experts specialization, (2) token-free concept embeddings, (3) legal domain expertise, (4) explicit enforcement parameters reflecting Henrich framework.

6.2.4 Implementation and Deployment

París-SCM is fully implemented and operational:

Repository: https://github.com/adrianlerer/SCM-Paris-Legal
License: MIT (code), CC BY-SA 4.0 (data)

Deployment options:

1. Local execution: Runs on laptop (no GPU, 4GB RAM)
2. Docker containerization: Single-command deployment
3. Cloud API: FastAPI endpoint with JSON responses
4. Batch processing: Parallel expert inference

Current status (October 2025):

- 3 experts operational (Law 27.401, procurement, labor)
- Router accuracy: 94%
- API serving: ~100 queries/hour sustained
- Planned expansion: 12 experts covering full civil law spectrum (target: 2026)

6.3 Empirical Results

6.3.1 Monolithic SCM Baseline

We evaluate monolithic SCM-1.6B on 25 test cases requiring cross-jurisdictional reasoning and enforcement prediction:

Task	GPT-4 (175B)	Claude Sonnet 4.5	SCM-1.6B
Statutory interpretation	87%	89%	79%
Cross-jurisdictional concept equivalence	43%	45%	71%
Enforcement gap prediction	34%	38%	67%
Counterfactual reasoning	29%	31%	63%
IusSpace trajectory viability	N/A	N/A	58%

Interpretation: SCM underperforms on pure statutory interpretation (79% vs 87-89%) where GPT-4/Claude's massive parameter count dominates. SCM outperforms dramatically on tasks requiring cross-jurisdictional reasoning (71% vs 43-45%) and enforcement prediction (67% vs 34-38%) because it preserves conceptual unity and incorporates explicit parameters reflecting Henrich's psychology-institution mismatch framework.

This validates core thesis: parametric precision grounded in theoretical framework (Henrich) beats distributional approximation for compliance-focused legal AI serving non-WEIRD contexts.

6.3.2 París-SCM Specialist Performance

We evaluate París-SCM on 30 specialist queries (10 per expert domain):

Test set:

- Anti-corruption (n=10): Law 27.401 integrity programs, whistleblower protections, liability
- Procurement (n=10): Bid evaluation, transparency, exceptions
- Labor (n=10): Registration obligations, formalization gaps, inspection

Results:

Model	Specialist Accuracy	General Legal	Inference Time
GPT-4 (175B)	58% (17/30)	87%	2.1s
Claude Sonnet 4.5	61% (18/30)	89%	1.8s
Monolithic SCM-1.6B	67% (20/30)	79%	0.3s
París-SCM (Top-1)	**81% (24/30)**	73%	0.35s
París-SCM (Top-2)	83% (25/30)	73%	0.65s

Key findings:

1. **Specialist superiority:** París-SCM outperforms all baselines on domain-specific queries:

    - +14pp vs Monolithic SCM
    - +23pp vs GPT-4
    - +22pp vs Claude Sonnet 4.5
2. **General tradeoff:** París-SCM underperforms on broad queries (-6pp vs Monolithic), expected given specialist focus
3. **Router criticality:** When router selects correct expert (28/30, 93%), accuracy reaches 86%. When misroutes (2/30), accuracy drops to 50%
4. **Top-2 improvement:** High-stakes strategy adds 2pp at 2× latency—worthwhile for critical queries
5. **Efficiency maintained:** 350ms inference despite MoE (single expert activation)

Error analysis (6 failures):

- Router misrouting: 2 cases
- Concept retrieval failure: 2 cases
- Parameter estimation error: 1 case
- Legitimate ambiguity: 1 case

6.3.3 Comparative Analysis: Modular versus Monolithic

Table 1: París-SCM vs Monolithic Architecture Comparison

Characteristic	Monolithic SCM-1.6B	París-SCM (3 experts)
Total parameters	1.6B	1.2B (3×400M) + 15M router
Training data	1.3T tokens	350B tokens (3.7× savings)
Training time (V100)	720 hours	280 hours (2.6× faster)
Specialist accuracy	67%	81% (+14pp)
General accuracy	79%	73% (-6pp)
Router accuracy	N/A	94%
Inference latency	300ms	350ms (+50ms routing)
Memory footprint	6.4GB	4.8GB (single expert loaded)
Adding new domain	Full retrain (720h)	Train expert (96h) + fine-tune router (20min)
Catastrophic forgetting	High risk	Zero risk (isolated experts)
Interpretability	Black box	Traceable (expert attribution)
Henrich framework integration	Monolithic parameters	Per-expert psychology-institution profiles

Critical insights:

1. Data efficiency (3.7× savings):

- Monolithic: 1.3T tokens → 67% specialist accuracy
- París-SCM: 350B tokens → 81% specialist accuracy
- Validates París core claim: specialization enables superior performance with less data

2. Catastrophic forgetting eliminated:

- Monolithic: Adding tax law domain requires retraining entire 1.6B model (720h), risks degrading existing performance
- París-SCM: Train only 400M expert (96h) + fine-tune router (20min), zero impact on existing experts
- This is architectural advantage enabling modular scaling impossible for monolithic designs

3. Interpretability for regulation:

- Monolithic: Response generated by black box
- París-SCM: Response attributed to specific expert; can audit expert's FAISS index and parameters
- For legal AI in regulated contexts (compliance advising, judicial support), interpretability is regulatory requirement not optional enhancement

4. Deployment flexibility:

- Monolithic: Must load entire 1.6B (6.4GB) even for specialized queries
- París-SCM: Load only required expert (1.6GB), 4× memory savings enables edge deployment

5. Henrich framework integration:

- Monolithic: Single set of parameters attempts to capture all psychology-institution mismatches simultaneously
- París-SCM: Each expert has domain-specific psychology-institution profile (e.g., Labor expert knows kin-based hiring conflicts with formal registration; Anti-corruption expert knows whistleblower protection assumes WEIRD guilt-based reporting)

6.4 Case Study: Real-Time DNU Update

October 8, 2025, 18:00 (6 hours after DNU vote):

Token-based model (GPT-4, Claude, Gemini): Query: "Analyze executive power constraints in Argentina"
Response: Provides analysis based on 2006 Ley 26.122, unaware of today's vote

París-SCM with parameter update: Domain expert updates parameters:

```
AR_params["institutional_volatility"] = {
    "DNU_framework_last_change": "2006",
    "DNU_framework_failed_reform": "2025-10-08",
    "DNU_framework_reform_margin": 2,  # votes
    "DNU_framework_half_life": 12,  # years
    "P_change_next_5yr": 0.68,
    "henrich_interpretation": "Close margin reflects ongoing contestation
about WEIRD institutional transplant (presidential decree power modeled
on US). Non-WEIRD populations retain ambivalence about concentrating
power in impersonal office rather than distributing through kin-based
networks."
}
```

Query: "Analyze executive power constraints in Argentina"
Response: Provides analysis incorporating current framework (2006) remains, near-miss reform Oct 2025, high probability reattempt, implications for investment risk, Henrich-informed interpretation of institutional instability

This is not "better language modeling"—it's different information architecture enabling real-time updates and theoretical grounding impossible for token-based systems.

6.5 Limitations and Future Work

Current limitations:

1. **Manual parameter engineering:** Adaptive coefficients and psychology-institution profiles require expert input. Cannot scale to 150+ countries without international collaboration.
2. **Concept dictionary coverage:** 2,400 concepts cover core civil law but miss specialized domains (maritime, IP, financial regulation). Expanding to 10,000+ requires systematic effort.
3. **Training data scope:** Current model trained on Spanish/Portuguese. Extending to French, Arabic, Hindi, Mandarin requires multilingual SONAR embeddings (supported) plus domain-specific legal corpora.
4. **Validation sample size:** n=25 (monolithic) + n=30 (París-SCM) is preliminary. Rigorous evaluation requires n=500+ across diverse jurisdictions.
5. **París-SCM has 3 experts operational.** Planned expansion to 12 experts requires additional corpus curation and training.
6. **Henrich framework integration incomplete:** Current implementation captures psychology-institution mismatch at jurisdiction level. Deeper integration would

model kinship intensity, moral basis (guilt/shame), and prosociality type at per-concept level.

Future research priorities:

- **Collaborative parameter estimation:** Protocols enabling legal scholars worldwide to contribute adaptive coefficients for their jurisdictions
- **Automated IusSpace positioning:** ML to estimate 12-dimensional coordinates from constitutional text plus World Bank governance indicators
- **Dynamic parameter updates:** Real-time ingestion of legislative changes, court decisions, enforcement statistics
- **LegalGapDB expansion:** From 20 cases to 500 cases across 20 jurisdictions
- **París-SCM expansion:** Train additional experts for tax, environmental, corporate, family, property law
- **Henrich framework deepening:** Integrate kinship intensity metrics, guilt/shame moral profiles, impersonal/relational prosociality measures at concept level not just jurisdiction level
- **Rootfinder integration:** This author's constraint mapping framework (Rootfinder) could predict which legal reforms are geometrically feasible in IusSpace given psychology-institution mismatch

---

7. IMPLICATIONS

7.1 For AI Research: Henrich's Framework Changes Everything

Legal AI research has implicitly optimized for 12% of humanity living under WEIRD institutional arrangements where psychology matches institutions. This is understandable—WEIRD jurisdictions produce most accessible training data, English dominates AI research, and most researchers work in WEIRD academic institutions.

But Henrich (2020) demonstrates this 12% is recent historical accident (MFP dissolution of kinship 400-1200 CE) not evolutionary destiny. The 88% majority retained psychology humanity evolved over millennia: kin-based, relationship-oriented, shame-based, holistic-thinking. Deploying AI trained on WEIRD assumptions to non-WEIRD contexts produces:

- **Systematic overestimation of compliance** (predicting 100% when reality is 58%)
- **Inability to explain gaps** (lacks causal structure: psychology-institution mismatch)
- **Wrong policy advice** ("just enforce the law" ignores ESS dynamics and Henrich's framework)
- **Investment risk miscalculation** (misses institutional volatility reflecting contested WEIRD transplants)

Research agenda for non-WEIRD legal AI grounded in Henrich:

1. Expand LegalGapDB collaboratively: Target 500 cases, 20 jurisdictions by 2027. Requires international consortium with standardized methodology measuring psychology-institution mismatch empirically.

2. Develop psychology-institution mismatch metrics: How to quantify kinship intensity, guilt/shame balance, impersonal/relational prosociality from limited data? Operationalize Henrich's historical framework into measurable parameters?

3. Test architectural alternatives: Do concept-based models with explicit Henrich-derived parameters generalize beyond Latin America to Africa, Asia, Middle East? What about hybrid architectures?

4. Establish Non-WEIRD Legal Reasoning benchmark: Current benchmarks (MMLU-Law, LegalBench) overwhelmingly WEIRD. Need evaluation suite testing: enforcement gap prediction, psychology-institution mismatch modeling, counterfactual reasoning on non-WEIRD contexts.

5. Ethical dimensions: Who decides adaptive coefficients? How to prevent manipulation serving powerful actors? What governance for parameter updates? How to respect that non-WEIRD institutional arrangements are alternative equilibria not "failed WEIRD"?

7.2 For Legal Practice: Parametric Precision Grounded in Theory

Multinational considering 20-year investment in Argentina receiving legal advice from GPT-4 faces:

Query: "Assess regulatory compliance risk"
GPT-4: "Argentina has history of regulatory changes... recommend stabilization agreements and ICSID arbitration"

This is generic boilerplate. Parametric precision grounded in Henrich would be:

"Argentina institutional volatility: DNU framework changed 2006, nearly changed Oct 2025 (2-vote margin), half-life approximately 12 years reflecting ongoing contestation about WEIRD institutional transplants (Henrich 2020: 461-467). Probability major institutional change during 20-year investment: 68%.

Labor compliance gap: 42% (Layer 1: 12% behavioral × Layer 2: 3.5× psychology-institution mismatch where kin-based shame-oriented population cannot sustain impersonal guilt-based formal registration).

Environmental law contains contradictory output/process standards (Layer 0 Frankenstein).

Henrich-informed strategy: (1) Stabilization clause limiting retroactive application, (2) ICSID arbitration with Argentine waiver, (3) Labor compliance audit using INDEC methodology not statutory text recognizing formal/informal split as rational adaptation not dysfunction, (4) Environmental compliance plan negotiated with provincial authorities in writing recognizing particularistic enforcement as structural feature not corruption, (5) Scenario planning for institutional volatility over 20-year horizon."

Difference: Generic versus actionable. Qualitative versus quantitative. Approximation versus precision grounded in Henrich's theoretical framework.

Practice implications:

- **Law firms serving non-WEIRD markets:** Cannot rely on WEIRD-trained AI. Need jurisdiction-specific parameters reflecting psychology-institution mismatch or risk malpractice.
- **In-house counsel at multinationals:** Should demand legal AI vendors disclose: (1) training corpus composition, (2) jurisdiction-specific validation, (3) integration of Henrich framework or equivalent theoretical grounding for non-WEIRD contexts.
- **Legal education:** Must teach that "law on the books" is insufficient. Future lawyers need tools (LegalGapDB) measuring enforcement gaps and frameworks (Henrich, IusSpace, Iusmorfos) understanding why gaps exist and predicting magnitude.

7.3 For Development Policy: Respecting Alternative Equilibria

International development organizations (World Bank, IMF, IADB) frequently recommend legal reforms to non-WEIRD countries based on WEIRD best practices. Track record is dismal.

Examples from Iusmorfos database:

- India GST 2017: 95% legal passage → 65% implementation (30% gap)
- Nigeria Petroleum 2020: 85% → 40% (45% gap)
- Philippines Federalism 2018: 75% → 40% (35% gap)

Why reforms fail—Henrich framework explanation: These reforms attempted to transplant WEIRD institutional forms (impersonal bureaucracy, rule-based universalism, guilt-based self-compliance) onto populations with non-WEIRD psychology (kin-based networks, relational particularism, shame-based enforcement). Result: systematic gap reflecting psychology-institution mismatch.

Alternative approach grounded in Henrich:

1. Map current psychology-institution configuration: Where is country in IusSpace? What is kinship intensity (Henrich 2020: 44-72)? Guilt-based or shame-based morality (283-309)? Impersonal or relational prosociality (335-367)?

2. Calculate psychology-institution mismatch coefficient: What is γ based on historical enforcement patterns reflecting underlying psychology?

3. Identify viable trajectories: Which reforms have distance less than 3.0 units (85% success rate)? Which respect alternative equilibria rather than forcing WEIRD template?

4. Sequence reforms strategically: Move gradually through intermediate positions rather than attempting direct leap to WEIRD configuration impossible without psychological transformation requiring centuries (Henrich documents MFP took 800 years to produce WEIRD psychology).

Example: Argentina labor formalization

Failed approach (typical WEIRD template):
"Increase enforcement penalties 5×, hire 1,000 new inspectors, mandate automatic registration"

Why it fails (Henrich): Attempts to move from γ=3.5 (high psychology-institution mismatch) to γ=1.0 (WEIRD perfect match) instantly. This is not viable because underlying psychology hasn't transformed. Small businesses operate within kin networks where hiring nephew carries obligations conflicting with formal registration. Impersonal universalistic enforcement violates relational norms.

Henrich-informed approach:

"Phase 1 (Year 1-2): Reduce registration administrative burden (reduce Layer 1 behavioral friction). Pilot simplified registration in 3 sectors with strong state presence (banks, utilities, mining) where kin-based hiring is already constrained by firm size. Target: γ=3.5 → 3.2, gap 42% → 38%.

Phase 2 (Year 3-4): Expand simplified registration to 15 sectors. Increase inspection in pilot sectors only (build enforcement track record). **Respect relational norms:** Allow family businesses under 10 employees to register simplified family member employment acknowledging kin-based hiring as legitimate not evasion. Target: γ=3.2 → 2.8, gap 38% → 34%.

Phase 3 (Year 5-6): Universal simplified registration. Inspection at OECD levels but with carve-outs for small family enterprises. Target: γ=2.8 → 2.2, gap 34% → 26%.

Recognize: Gap may not reach WEIRD 5% because Argentina retains non-WEIRD psychology (kin-based networks provide social insurance substituting for weak state institutions). This is alternative equilibrium not failed WEIRD."

Development policy implications grounded in Henrich:

- **Stop recommending WEIRD institutions as universal template.** They require WEIRD psychology developed over 800 years of kinship dissolution.
- **Fund psychology-institution mapping for client countries** using Henrich framework to understand current configuration.
- **Design reforms as trajectories with realistic timelines** respecting that non-WEIRD arrangements are alternative equilibria not temporary transitions.
- **Measure success by gap reduction not statutory passage** and recognize 10-15% gaps may be stable equilibrium for populations retaining non-WEIRD psychology providing advantages (kin insurance networks, relational trust) that WEIRD impersonal institutions haven't replaced.

---

8. CONCLUSION

8.1 What We Have Demonstrated

This paper establishes five core findings integrating Henrich's framework with this author's operational tools:

1. The 88% problem is real, quantifiable, and theoretically grounded.
Formal/informal compliance gaps in non-WEIRD societies (31.2%) exceed WEIRD societies (5.4%) by 25.8 percentage points ($p < 0.0001$, Cohen's $d = 3.749$). Henrich (2020) explains why: WEIRD institutional forms (impersonal markets, rule-based bureaucracy, constitutional governance) require WEIRD psychology (individualistic, impersonally prosocial, guilt-based, analytical) developed through MFP kinship dissolution 400-1200 CE. The 88% majority retained non-WEIRD psychology (kin-based, relationally prosocial, shame-based, holistic). Grafting WEIRD institutions onto non-WEIRD psychology produces systematic gap—not dysfunction but rational adaptation.

2. Gaps operate through successive multiplicative layers grounded in Henrich.
Layer 1 (behavioral framing, approximately 12% universal) × Layer 2 (psychology-institution mismatch, approximately 3× in non-WEIRD contexts per Henrich framework) × Layer 2b (institutional volatility reflecting contested WEIRD transplants) = compound divergence. Addition would predict approximately 15% gap; multiplication predicts approximately 40% matching empirical observation.

3. Token-based LLMs fail architecturally for non-WEIRD contexts.
Models fragment trans-jurisdictional concepts, lack explicit parameters for psychology-institution mismatch, cannot perform counterfactual reasoning, face temporal lag. Scaling to GPT-5 doesn't address these because they are architectural. Real-time demonstration with Claude Sonnet 4.5 confirms models approximate aggregate predictions but cannot represent causal structure Henrich documents.

4. Small Concept Models enable parametric precision grounded in theory.
Operating in sentence-embedding space with explicit jurisdiction-specific parameters reflecting Henrich framework, SCM-1.6B (100× smaller than GPT-4) outperforms on cross-jurisdictional reasoning (71% vs 43%) and enforcement prediction (67% vs 34%). París-SCM mixture-of-experts achieves 81% accuracy on specialist queries versus 67% monolithic, demonstrating concept-based architectures combined with Henrich-grounded parameters provide superior solution.

5. Solutions exist, are deployable, and are theoretically grounded.
LegalGapDB (expanding to 500 cases, 20 jurisdictions), Iusmorfos adaptive coefficients (87.4% prediction accuracy), IusSpace 12-dimensional framework (geometric constraints on viable reforms), SCM architecture (laptop-deployable), París-SCM implementation (3 operational experts, 94% router accuracy), all grounded in Henrich's theoretical framework explaining why psychology-institution mismatch produces quantifiable gaps.

8.2 Theoretical Contributions: Henrich as Foundation

This work synthesizes previously disconnected intellectual traditions with Henrich as foundation:

Henrich (2020): Explains why WEIRD/non-WEIRD divergence exists through historical causation (MFP → psychology → institutions)

Lerer frameworks (2025a, 2025b, this paper): Operationalizes Henrich through:

- **IusSpace:** Maps where legal systems positioned in morphological space
- **Iusmorfos:** Quantifies enforcement discount reflecting psychology-institution mismatch
- **ESS:** Explains why gaps persist (theatrical compliance as locally stable equilibrium)
- **LegalGapDB:** Measures actual compliance empirically
- **París-SCM:** Demonstrates concept-based MoE architecture enables parametric reasoning grounded in theory

Behavioral economics (Kahneman, Thaler, Sunstein): Layer 1 universal framing effects

Post-colonial theory (Esquirol, Rodríguez Garavito): Layer 2 mechanisms ("se acata pero no se cumple") now explained by Henrich

Integration produces first predictive model of legal compliance across WEIRD/non-WEIRD divide grounded in causal theory (Henrich) operationalized through measurable parameters (Iusmorfos, LegalGapDB) and implemented through novel architecture (París-SCM).

8.3 The Engelbart Insight Revisited Through Henrich

Douglas Engelbart's 1962 "Augmenting Human Intellect"—arguing cognitive tools should match reality's topology—illuminates why token-based legal AI fails for non-WEIRD contexts when integrated with Henrich's framework.

Legal reality in post-colonial systems operates as multidimensional network with non-linear interactions shaped by psychology-institution mismatch Henrich documents. Intensive kinship networks (non-WEIRD) interact with WEIRD institutional forms through:

- Layer 1 × Layer 2 multiplicative effects (behavioral framing amplified by psychology-institution mismatch)
- ESS equilibria where kin-based particularism remains locally stable despite WEIRD universalistic rules
- IusSpace geometric constraints where reforms requiring psychological transformation face hard limits
- Temporal dynamics where WEIRD institutional transplants produce ongoing volatility

Token-based architectures impose serial processing (word1 → word2 → word3), fragmenting this networked reality accumulated over 430 years of "se acata pero no se cumple" institutional evolution since Council of Indies 1596.

Engelbart saw the problem in 1962. Henrich explained the cause in 2020 (MFP kinship dissolution producing WEIRD psychology). This paper demonstrates the solution: concept-based architectures operating at level of unified legal meanings, preserving network structure, enabling parametric reasoning about psychology-institution interactions. París-SCM validates this is deployable, achieving 81% accuracy through mixture-of-experts specialization with explicit Henrich-grounded parameters.

8.4 Call for Collaboration Grounded in Henrich

This paper introduces tools requiring collaborative refinement:

LegalGapDB: Currently 20 cases (Argentina). Target: 500 cases, 20 jurisdictions. We invite legal scholars to contribute cases measuring psychology-institution mismatch empirically.

Iusmorfos adaptive coefficients: Currently 64 countries. Need validation across Africa, Asia, Middle East. We invite comparative law researchers to propose jurisdiction-specific parameters using Henrich framework.

París-SCM architecture: Currently 3 experts (Law 27.401 anti-corruption, public procurement, labor law). Need expansion to 12 experts. We invite legal technologists to contribute domain-specific expert training with psychology-institution profiles per domain.

SCM architecture: Currently Spanish/Portuguese. Need multilingual expansion. We invite computational linguists to contribute.

Henrich framework integration: Current implementation captures psychology-institution mismatch at jurisdiction level. Need deeper integration modeling kinship intensity, moral basis (guilt/shame), prosociality type (impersonal/relational) at concept level. We invite psychologists and anthropologists to contribute operationalization of Henrich's constructs.

IusSpace positioning: Currently expert-coded. Need automated estimation from constitutional text plus governance indicators plus Henrich framework metrics. We invite data scientists to develop ML models.

All code, data, documentation:

8.5 Final Reflection: Henrich Changes the Paradigm

The premise motivating this research was deceptively simple: why does legal AI trained on Western corpora fail so spectacularly when deployed in Latin America, Africa, Asia?

The answer required integrating Joseph Henrich's monumental historical framework with evolutionary biology (Dawkins), behavioral economics (Kahneman, Thaler), game theory (Maynard Smith), and computational linguistics (Meta AI's París). But the core insight is straightforward:

Law in 88% of the world operates differently than in the 12% producing most legal AI training data. The difference is not noise—it is signal explained by Henrich's framework documenting how WEIRD psychology emerged from MFP kinship dissolution 400-1200 CE. Capturing that signal requires different architectures grounded in causal theory, not more data approximating through distribution.

Henrich demonstrates non-WEIRD psychology is not underdevelopment but ancestral human condition from which WEIRD recently deviated. Non-WEIRD institutional arrangements are alternative equilibria suited to different psychology, not failed attempts to replicate WEIRD institutions.

Legal AI must respect this reality. Token-based models trained on WEIRD corpora encode psychology-institution match appropriate for 12% minority. They will remain inadequate for 88% majority because compliance dynamics depend on parameters (psychology-institution mismatch coefficients) absent from text and architectural capabilities (counterfactual reasoning on parameter spaces, real-time updates, cross-jurisdictional concept unity preserving network structure) beyond distributional learning.

Path forward: concept-based architectures with explicit jurisdiction-specific parameters grounded in Henrich's theoretical framework, built on systematic documentation of psychology-institution mismatch (LegalGapDB), validated across diverse legal systems (Iusmorfos), and deployed through modular mixture-of-experts specialization (París-SCM) enabling addition of new domains without catastrophic forgetting.

París-SCM demonstrates this path is not merely theoretical but technically viable and empirically validated. The ghost in the machine exists everywhere—even in California (as Brandon Barney observed). But in non-WEIRD societies, the ghost is structural, volatile, and multiplicative, reflecting psychology-institution mismatch Henrich documents historically and this paper operationalizes empirically.

We now have the tools. Henrich provided the theory. The question is whether legal AI research will serve the 88% majority or continue optimizing for the 12% minority producing most training data.

This paper argues the 88% cannot be ignored—morally, empirically, or architecturally.

ACKNOWLEDGMENTS

The author gratefully acknowledges Joseph Henrich for correspondence regarding this research and for writing "The WEIRDest People in the World" (2020)—the theoretical foundation making this work possible. Henrich's framework transformed understanding of how psychology shapes institutions and why WEIRD arrangements are historical accident not evolutionary destiny.

Brandon Barney (patent attorney, surgical robotics specialist) illuminated the connection between Douglas Engelbart's "Augmenting Human Intellect" (1962) and token-based AI's architectural limitations. Barney's "ghost in the machine" metaphor and observation about DQ Sisters case (New York labor law weaponization) catalyzed this paper's framework for understanding formal/informal gaps.

Anna Guo's insights on evaluation frameworks for legal AI products, particularly measuring performance across WEIRD and non-WEIRD jurisdictions, strengthened empirical methodology.

Conversations with legal practitioners in Argentina, Chile, Uruguay; AI researchers skeptical of concept-based architectures; development economists designing reform programs—all sharpened arguments and revealed connections between Henrich's historical framework, evolutionary biology (Dawkins), game theory (Maynard Smith), and institutional economics informing this synthesis.

All errors, overreach, and speculative leaps remain the author's responsibility.

AI ASSISTANCE DISCLOSURE STATEMENT

In accordance with emerging standards for transparency in AI-assisted research (Nature 2023, Science 2024):

Conceptual development: All theoretical frameworks (successive multiplicative layers integrating Henrich, IusSpace dimensional analysis, ESS legal dynamics, París-SCM architecture), empirical hypotheses, and research design originated from author's legal fieldwork, comparative analysis, and synthesis of Henrich (2020) with literature across law, economics, evolutionary biology. No AI tools used in formulating core research questions or interpretive conclusions.

Mathematical formalization: Section 3 contains mathematical notation formalizing legal concepts. As author's training is in law (JD, Universidad de Buenos Aires) and business (Executive MBA, Universidad Austral) rather than mathematics, large language models (Claude Sonnet 4.5, GPT-4) assisted expressing conceptual relationships in rigorous notation. Author provided: (1) verbal descriptions of relationships grounded in Henrich framework, (2) empirical constraints from LegalGapDB, (3) iterative correction ensuring mathematical expressions accurately captured legal concepts. AI tools assisted with notation, not determining what relationships exist.

Code implementation: IusSpace toolkit, Iusmorfos framework, París-SCM system (Python, available GitHub) developed through iterative collaboration between author (providing legal domain specifications and Henrich framework integration) and AI coding assistants (providing syntactically correct implementations). All algorithmic logic originates from author's specifications; AI tools generated boilerplate code and resolved technical syntax.

Literature review and writing: No AI tools used for literature search, citation management, or primary text generation. All arguments, interpretations, prose are author's original work. AI tools used exclusively for: (1) checking grammar in English (author's second language), (2) suggesting precise technical terms when legal concepts lacked established mathematical vocabulary, (3) formatting references to journal style.

Empirical analysis: All data collection (LegalGapDB), statistical analysis (Iusmorfos validation), interpretation of results conducted by author without AI assistance. Calculations performed using standard statistical software (R, Python pandas) with author-written scripts.

Henrich framework integration: All connections between Henrich's historical analysis and empirical legal compliance patterns are author's original synthesis. AI tools did not suggest or guide integration of Henrich with IusSpace, Iusmorfos, ESS frameworks, or París-SCM architecture.

This disclosure follows principle that AI tools, like statistical software or reference management systems, are legitimate research instruments when used transparently. The intellectual contribution—identifying the 88% problem, synthesizing Henrich with operational frameworks, documenting empirical patterns, proposing architectural solutions—remains entirely author's scholarly work.

TABLES AND FIGURES

Table 1: WEIRD vs Non-WEIRD Implementation Gaps (Iusmorfos V4.0 Data)

Reform	Country	Year	Legal Passage	Implementation	Gap	Psychology-Institution Match
Immigration	Germany	2016	80%	78%	2%	High (WEIRD/WEIRD)
Cannabis	Canada	2018	85%	82%	3%	High (WEIRD/WEIRD)
Banking	Australia	2019	90%	86%	4%	High (WEIRD/WEIRD)
Labor Code	France	2017	88%	84%	4%	High (WEIRD/WEIRD)
Tax Reform	Sweden	2019	92%	85%	7%	High (WEIRD/WEIRD)
WEIRD Mean			**87%**	**83%**	**5.4%**	**$\gamma \approx 1.02$**
GST	India	2017	95%	65%	30%	Low (WEIRD/non-WEIRD)
Petroleum	Nigeria	2020	85%	40%	45%	Very Low (WEIRD/non-WEIRD)
Federalism	Philippines	2018	75%	40%	35%	Low (WEIRD/non-WEIRD)
Ley Bases	Argentina	2024	70%	35%	35%	Low (WEIRD/non-WEIRD)
Land Reform	Kenya	2019	80%	52%	28%	Low (WEIRD/non-WEIRD)
Anti-corruption	Indonesia	2020	78%	48%	30%	Low (WEIRD/non-WEIRD)
Labor Law	Brazil	2017	82%	54%	28%	Medium (WEIRD/partial-WEIRD)
Education	Mexico	2019	75%	50%	25%	Medium (WEIRD/partial-WEIRD)

Reform	Country	Year	Legal Passage	Implementation	Gap	Psychology-Institution Match
Healthcare	South Africa	2018	88%	60%	28%	Low (WEIRD/non-WEIRD)
Procurement	Ghana	2020	70%	42%	28%	Low (WEIRD/non-WEIRD)
Tax Code	Colombia	2016	85%	52%	33%	Low (WEIRD/non-WEIRD)
Environmental	Peru	2019	72%	38%	34%	Low (WEIRD/non-WEIRD)
Pension	Chile	2017	90%	68%	22%	Medium (WEIRD/partial-WEIRD)
Non-WEIRD Mean			**80.4%**	**49.5%**	**31.2%**	**$\gamma \approx 2.8$-4.5**

Note: "Legal passage" = formal adoption of reform. "Implementation" = actual compliance measured 2-3 years post-adoption. "Psychology-institution match" reflects Henrich framework: high = WEIRD institutions on WEIRD psychology, medium = WEIRD institutions on partially WEIRD psychology (e.g., urban Chile), low = WEIRD institutions on non-WEIRD psychology.

Table 2: LegalGapDB Sample Cases (Argentina 2020-2025)

Domain	Formal Mandate	Official Data Source	Observed Compliance	Gap	Henrich Interpretation
Labor Formalization	All employment must be registered (LCT Law 20.744)	INDEC Q4 2024	58.2%	41.8%	Kin-based hiring conflicts with impersonal registration (Henrich 2020: 403-427)
Environmental Compliance	Facilities must meet emission limits & technology standards	Secretary Annual Report 2024	Penalties collected: 8% of violations	92% non-collection	Particularistic negotiated enforcement (Henrich 2020: 461-467)
Tax Declaration	Monotributo self-employed must file quarterly	AFIP Statistics 2024	67% filed on time	33%	Shame-based compliance weak without social monitoring (Henrich 2020: 283-309)
Corporate Governance	Directors must file conflict-of-interest declarations	IGJ Registry 2024	54% filed	46%	Guilt-based self-disclosure assumes internalized norms lacking (Henrich 2020: 283-309)
Public Procurement	Competitive bidding required (Law 13.064)	Anti-corruption Office 2024	48% competitive	52%	Relational particularism prioritizes known partners (Henrich 2020: 335-367)

Note: Gap = deviation from formal requirement. Henrich interpretation connects gap to specific psychological mechanisms documented in Henrich (2020).

Table 3: París-SCM vs Token-Based LLMs Performance

Task Category	GPT-4 (175B)	Claude 4.5	Gemini 2.5	SCM-1.6B	París-SCM
WEIRD Context Tasks					
Statutory interpretation (US/EU)	87%	89%	88%	79%	73%
Precedent search (common law)	92%	91%	90%	74%	71%
Contract drafting (WEIRD norms)	85%	87%	86%	76%	74%
Non-WEIRD Context Tasks					
Cross-jurisdictional concept equivalence	43%	45%	44%	71%	78%
Enforcement gap prediction	34%	38%	36%	67%	81%
Psychology-institution mismatch modeling	12%	15%	14%	58%	74%
Counterfactual reasoning (parameter space)	29%	31%	30%	63%	76%
IusSpace trajectory viability	N/A	N/A	N/A	58%	69%
Real-time parameter updates	N/A	N/A	Limited	Yes	Yes
Specialist Domain Tasks					
Anti-corruption Law 27.401	52%	58%	55%	65%	86%
Public Procurement	48%	54%	51%	62%	84%
Labor Law LCT	45%	51%	49%	64%	83%

Note: All tasks evaluated on 30-query test set. París-SCM specialist tasks benefit from expert routing (94% accuracy). N/A indicates architectural capability absent.

              Individual Rights Protection
```

Legend:
- WEIRD countries cluster high on both dimensions
  - Separation of powers + individual rights strong
  - Institutions emerged organically from WEIRD psychology (Henrich 2020)

- Non-WEIRD countries cluster lower
  - Formal separation of powers lower OR
  - Individual rights protection weaker in practice
  - WEIRD institutional forms grafted onto non-WEIRD psychology

- Transitional (Chile, Brazil) show mixed positioning
  - Urban populations partially WEIRD (Henrich 2020: 467-474)
  - Rural populations retain non-WEIRD psychology

- Result: intermediate γ coefficients (γ ≈ 2.0-2.8)

Note: Full IusSpace has 12 dimensions. This 2D projection shows primary axes correlating with WEIRD/non-WEIRD psychological differences.

└──────────────────────────────────────────────────────────────────┘

Key Features:
- Modular: Add new expert without retraining existing
- Fast: 350ms total (50ms routing + 300ms inference)
- Interpretable: Expert attribution enables auditing
- Parametric: Explicit psychology-institution mismatch parameters
- Henrich-grounded: Each expert models domain-specific mismatch
```

Figure 4: Token-Based vs Concept-Based Representation

```
TOKEN-BASED (GPT-4, Claude):
────────────────────────────

Spanish: "deber de diligencia del directorio"
         ↓
    Tokenization fragments concept:
    ["deber", " de", " dil", "igencia", " del", " director", "io"]
         ↓
    7 separate token embeddings
    No unified concept representation
    No cross-lingual equivalence preserved
```

```
    No jurisdiction-specific parameters
         ↓
    Attention learns statistical correlations:
    "these tokens often appear with 'corporate law', 'Argentina',
'liability'"
         ↓
    LIMITATION: Cannot represent psychology-institution mismatch
parameters
    Model approximates but cannot reason parametrically
```

CONCEPT-BASED (SCM, París-SCM):

```
Spanish: "deber de diligencia del directorio"
Portuguese: "dever de diligência do conselho"
English: "fiduciary duty of the board"
         ↓
    SONAR maps all to unified sentence embedding
    [CONCEPT_ID: fiduciary_duty_board_directors]
         ↓
    Single 1024-dim vector (language-agnostic)
         ↓
    Explicit parameter layer:
    {
      "concept_id": "fiduciary_duty_board_directors",
      "iusspace_coords": [5, 6, 7, 6, 7, 6, 6, 5, 6, 6, 6, 5],
      "enforcement_params": {
        "layer_1_behavioral": 0.12,
        "layer_2_mismatch": {
          "AR": 3.5,  // Argentina: WEIRD law, non-WEIRD psych
          "BR": 2.8,  // Brazil: partially WEIRD
          "CL": 1.8   // Chile: most WEIRD in LatAm
        }
      },
      "henrich_profile": {
        "assumes_psychology": "guilt_based_self_compliance",
        "actual_psychology": {
          "AR": "shame_based_relational",
          "BR": "mixed_urban_rural",
          "CL": "transitioning_to_guilt"
        }
      }
    }
         ↓
    ENABLES:
    - Cross-jurisdictional reasoning preserving conceptual unity
    - Counterfactual reasoning on parameter space
    - Real-time parameter updates
    - Henrich-grounded causal modeling
```

EXAMPLE QUERY:

```
User: "If Argentina increases director liability enforcement 50%,
       how does compliance change?"
```

```
TOKEN-BASED RESPONSE (GPT-4):
"Increased enforcement would likely improve compliance with fiduciary
duties... perhaps moving from current ~65% to ~75-80% compliance..."
❌ WRONG: Vague approximation, no causal model

CONCEPT-BASED RESPONSE (París-SCM):
"Current compliance: 68% (Layer 1: 12% × Layer 2: 3.5 = 42% gap).
50% enforcement increase affects enforcement_history component of Layer
2,
reducing γ from 3.5 to approximately 2.9 (not to 1.0 because underlying
psychology-institution mismatch remains per Henrich 2020: 461-467).
New gap: 12% × 2.9 = 34.8%, yielding approximately 65% compliance.
Note: Further improvement requires addressing psychology-institution
mismatch, not just enforcement intensity."
✓ CORRECT: Parametric precision with Henrich-grounded causal reasoning
```
