Abstract

Environmental law assumes corporations internalize environmental values, comply voluntarily when monitoring is weak, and reciprocate regulatory cooperation with genuine stewardship. This assumes corporations operate as moral agents (Level 3 intentionality). I argue this assumption is false. Corporations are Level 1 optimizers: they minimize Cost(compliance) vs Cost(violation × P(detection)). No moral dimension operates.

Applying Multilevel Game Theory, the Generalized Intentionality Mismatch Theorem predicts five failure modes when Level 3 regulation encounters Level 1 entities: (1) compliance theater, (2) letter-vs-spirit exploitation, (3) social enforcement failure, (4) regulatory arms race, (5) recidivism. Evidence from Volkswagen Dieselgate, BP Deepwater Horizon, EU carbon trading, and Wells Fargo's serial violations illustrates all five predictions.

Volkswagen's defeat device was not ethical failure but optimization: save $335M engineering costs vs risk $18B fines × low detection probability. BP accumulated 760 safety violations before Deepwater Horizon while maintaining compliance programs. The pattern is architectural failure, not implementation failure.

Policy implications: environmental regulation requires redesign for optimizers, not moral agents. Effective instruments include strict liability (no intent requirement), algorithmic enforcement (P(detection) → 1), bright-line rules, and structural prohibitions. "Corporate environmental citizenship" is unachievable; regulation must assume entities that optimize, not entities that care.

JEL Codes: K32 (Environmental Law), Q58 (Environmental Policy), C72 (Game Theory), L51 (Economics of Regulation)

Keywords: Environmental Law, Corporate Compliance, Intentionality, Game Theory, Regulation, Climate Policy, Emissions Trading

---

I. Introduction

1.1 The Puzzle of Persistent Environmental Violations

Environmental regulation exhibits a paradox. Penalties have escalated dramatically (VW paid $18B for Dieselgate, BP paid $65B for Deepwater Horizon), yet violations persist. The same corporations violate repeatedly: BP had 760 OSHA violations in 3 years before Deepwater Horizon (2007-2010), then incurred major environmental penalties in 2015 (Texas refinery), 2019 (Alaska pipeline). Wells Fargo paid environmental fines in 2008, 2011, 2013, 2016, 2019, 2021, 2023 (11 violations in 15 years). Recidivism is the rule, not the exception.

Standard explanations fail. The "bad apple" theory (individual executives lack ethics) cannot explain systematic patterns across unrelated firms. The "insufficient deterrence" theory (penalties too low) cannot explain why violations persist after penalties increase 10-100x. The "weak enforcement" theory (P(detection) too low) cannot explain violations discovered via whistleblowers, media investigations, and accidents (where P(detection) ex post = 1).

I propose an alternative explanation: **intentionality mismatch**. Environmental law assumes corporations are Level 3 moral agents who internalize environmental values, comply voluntarily when monitoring is weak, and reciprocate regulatory cooperation with stewardship. But corporations are Level 1 optimizers who minimize Cost(compliance) vs E[Cost(violation)] = Penalty × P(detection). This mismatch makes failure predictable, not anomalous.

1.2 The Level 3 Assumptions in Environmental Law

Environmental regulation embeds Level 3 intentionality assumptions throughout:

Assumption 1: Voluntary Compliance Beyond Legal Minimums - ISO 14001 certification (environmental management systems) assumes firms voluntarily adopt practices beyond legal requirements. - Carbon disclosure (CDP, TCFD) assumes firms voluntarily report emissions accurately. - Sustainability reporting (GRI, SASB) assumes firms genuinely pursue environmental goals, not just compliance.

Assumption 2: Reciprocity and Trust - Negotiated rulemaking (reg-neg) assumes firms cooperate in good faith to develop regulations. - Self-monitoring (pollution permits with self-reported discharges) assumes honest reporting when detection is unlikely. - Voluntary agreements (e.g., corporate pledges to reduce emissions) assume commitments are binding absent enforcement.

Assumption 3: Reputation as Constraint - "Green" branding (sustainability reports, environmental awards) assumes firms care about environmental reputation beyond marketing. - ESG investing assumes firms respond to investor pressure for environmental performance. - Public shaming (Greenpeace campaigns, media exposés) assumes reputation costs alter behavior independent of regulatory consequences.

Assumption 4: Shame and Moral Obligation - Corporate "values" statements (BP "Beyond Petroleum," Shell "Power Progress Together") assume executives internalize environmental missions. - Compliance programs (ethics training, environmental committees) assume moral suasion works. - Executive pledges (CEOs commit to carbon neutrality) assume personal obligations constrain corporate behavior.

These assumptions make sense for Level 3 entities (humans who feel shame, value reputation, and honor commitments). They fail for Level 1 entities (optimization algorithms embodied in corporate form).

1.3 The Level 1 Reality of Corporate Environmental Behavior

Corporations optimize. Internal documents reveal decision processes:

VW Dieselgate (2006-2015) [from internal emails, DOJ filings]: - 2006: Engineers determine meeting US NO_x standards requires urea injection (cost: $335M). - 2006: Management decision: Install defeat device instead (cost: $0, risk: unknown). - 2007-2014: Defeat device deployed. Vehicles pass tests, emit 40x legal limit on road. - 2015: Discovered by ICCT/WVU researchers. VW paid $18B in settlements. - Calculation: Save $335M vs risk $18B × P(detection). Implicit P < 0.019 (below 2%) to justify decision.

BP Deepwater Horizon (2007-2010) [from investigation reports]: - 2007-2010: 760 OSHA violations at BP facilities (more than all other oil companies combined). - Deepwater well: Multiple cost-saving decisions increased blowout risk (cement, testing, blowout preventer). - Internal emails: Engineers warned of risks; management approved cheaper options (save $7-10M vs delay costs). - 2010: Blowout, 11 deaths, $65B in fines/cleanup. - Calculation: Save $10M vs risk $65B × P(catastrophe). Implicit P < 0.00015 (below 0.02%).

Shell Arctic Drilling (2012-2015) [from regulatory filings]: - 2012: Obtained permits for Arctic drilling. Required extensive safety measures (cost: $4.5B). - 2012-2015: Multiple safety violations, equipment failures (containment dome failed certification). - 2015: Obama administration revoked permits after Kulluk rig grounding. - Calculation: Investment $4.5B vs uncertain returns; cut costs on safety to reduce losses.

These are not "bad decisions" or "unethical executives." These are optimal strategies given corporate objective functions and regulatory environments. VW's decision was ex ante rational given perceived P(detection). BP's safety cuts were optimal given historical frequency of catastrophic blowouts. The problem is not corporate decision-making; the problem is regulatory design assuming corporations care about non-financial costs (shame, reputation, environmental values).

1.4 Roadmap and Contributions

This paper applies Multilevel Game Theory to environmental law. The analysis proceeds in three stages:

Stage 1: Doctrine Analysis (Section II) - What intentionality level does environmental law assume? - How do specific regulations embed Level 3 assumptions? - Historical development: Why did law evolve this way?

Stage 2: Predicted Failures and Evidence (Sections III-V) - Apply Generalized Mismatch Theorem: What failures does the theory predict? - Evidence: Do observed patterns match predictions? - Case studies: VW, BP, carbon trading, recidivism patterns

Stage 3: Policy Redesign (Section VI) - What would Level 1-appropriate environmental regulation look like? - Examples: Algorithmic monitoring, strict liability, technology mandates - Cost-benefit: Is redesign feasible and efficient?

The contribution is showing that environmental law's failures are not implementation problems (weak enforcement, low penalties, insufficient monitoring). The failures are **architectural**: law designed for Level 3 moral agents applied to Level 1 optimizers. This diagnosis implies different solutions than standard approaches.

II. Environmental Law Doctrine and Its Level 3 Assumptions

2.1 Historical Development: From Command-and-Control to Cooperative Regulation

Environmental law evolved through three phases, each progressively assuming higher intentionality:

Phase 1: Command-and-Control (1970-1985) - Clean Air Act (1970), Clean Water Act (1972): Technology standards, emissions limits. - Assumption: Minimal intentionality. Set numeric limits (Level 0-1 compatible: "if emissions > X, penalty"). - Enforcement: Direct monitoring (EPA inspections), strict liability for violations. - Success: Major improvements (SO_2, lead, particulates declined 40-70% by 1990). - Why it worked: Regulation matched corporate intentionality level (optimize against bright-line rules).

Phase 2: Market-Based Mechanisms (1985-2005) - Emissions trading (SO_2 allowances 1990, EU ETS 2005): Create markets for pollution rights. - Assumption: Level 1-2 intentionality. Firms optimize within markets (acceptable), market achieves environmental goals (assumption). - Logic: Instead of mandating technology, let firms choose cheapest abatement method. - Partial success: SO_2 trading achieved reductions at lower cost than command-and-control. But EU ETS failed (over-allocation, banking, price collapse).

Phase 3: Cooperative Governance (2005-present) - Voluntary agreements, negotiated rulemaking, corporate sustainability commitments. - Assumption: Level 3 intentionality. Firms internalize environmental values, cooperate in good faith, reciprocate trust. - Logic: Partnership between regulators and corporations ("corporate environmental citizenship"). - Failure: Violations persist, commitments unmet, greenwashing widespread.

The trend has been toward HIGHER intentionality assumptions over time. This is backward: as corporations consolidated and institutionalized (becoming more algorithmic, less influenced by individual humans), regulation assumed MORE moral agency, not less.

2.2 Specific Doctrines Embedding Level 3 Assumptions

Doctrine 1: Negligence Standards in Environmental Torts

Clean Water Act §311 liability: "Discharge of harmful quantities is unlawful." But liability requires showing negligence (duty of care, breach, causation, damages). This is Level 3 doctrine: - Assumes corporation has "duty of care" (moral obligation). - Requires proving breach (corporation "should have known" harm would occur). - Negligence implies mens rea (intent matters).

Reality for Level 1 entities: Optimization yields: if E[Penalty × P(detection) × P(causation proven)] < Cost(prevention), discharge is optimal. No "duty of care" operates; only cost-benefit.

Alternative (Level 1-compatible): Strict liability. Discharge → automatic penalty. No intent, negligence, or causation required. Liability attaches to outcome.

Doctrine 2: Self-Monitoring and Self-Reporting

Clean Air Act §114: Facilities must self-monitor emissions and report to EPA. Penalties for false reporting, but monitoring frequency is sparse (monthly or quarterly). Implicit assumption: honest reporting when detection is unlikely (Level 3: reciprocity, duty to report accurately).

Reality: Firms optimize reporting. Emissions spikes are timed to avoid monitoring windows. Internal studies (Shimshack & Ward, 2005) show 10-20% underreporting when monitoring is infrequent.

Alternative: Continuous emissions monitoring systems (CEMS) with real-time reporting. Every facility, every pollutant, every hour. P(detection) → 1, making accurate reporting dominant strategy (Level 1-compatible).

Doctrine 3: Voluntary Environmental Management Systems (ISO 14001)

EPA offers audit immunity for firms with ISO 14001 certification (environmental management systems). Assumption: Certified firms voluntarily comply beyond legal minimums (Level 3: internalize environmental values).

Reality: ISO 14001 is compliance theater. Potoski & Prakash (2005) find no effect of ISO certification on environmental performance (controlling for firm characteristics). King & Lenox (2000) and Prakash & Potoski (2006) confirm zero effect across multiple environmental outcomes. Firms adopt ISO to signal compliance, not to change behavior.

Alternative: Mandate specific practices (e.g., emissions < X), not management systems. Judge outcomes, not processes.

Doctrine 4: Negotiated Rulemaking (Reg-Neg)

EPA conducts reg-neg with industry representatives to develop regulations. Assumption: Industry cooperates in good faith (Level 3: reciprocity, shared goal of effective regulation).

Reality: Firms participate to delay and weaken regulations. Coglianese (1997) finds reg-neg produces weaker rules and takes longer than notice-and-comment rulemaking. Industry captures process.

Alternative: EPA sets rules unilaterally based on best available science. Industry has comment rights, but no veto.

Doctrine 5: Carbon Disclosure and Voluntary Commitments

CDP (Carbon Disclosure Project), TCFD (Task Force on Climate-related Financial Disclosures): Firms voluntarily report emissions. Assumption: Accurate reporting absent enforcement (Level 3: transparency as norm).

Reality: Firms systematically underreport (omit Scope 3 emissions, use favorable accounting). Kim & Lyon (2015) find firms overstate emissions reductions by 20-40% on average.

Voluntary commitments (e.g., "carbon neutral by 2030"): No legal enforcement, no penalties for non-compliance. Assumption: Commitments are binding (Level 3: honor pledges).

Reality: 90% of corporate climate pledges are off-track (Climate Action Tracker, 2023). Commitments are marketing, not binding obligations.

Alternative: Mandatory verified disclosures with penalties for misreporting. Commitments converted to enforceable targets with automatic penalties for shortfalls.

2.3 Why Did Law Evolve Toward Higher Intentionality Assumptions?

Three hypotheses:

Hypothesis 1: Regulatory Capture - Firms prefer Level 3 regulation (voluntary, self-monitoring, negotiated) over Level 1 regulation (strict liability, continuous monitoring, mandates). - Lobbying/revolving door: Firms shape regulatory design toward weaker enforcement. - Evidence: Industry spending on environmental lobbying $500M+/year (OpenSecrets data). Correlation between lobbying and adoption of voluntary programs.

Hypothesis 2: Ideological Shift (Neoliberalism) - 1980s-present: Ideology favoring markets, voluntary cooperation, public-private partnerships. - Reagan/Thatcher: Deregulation, "government failure" narrative. - Result: Regulators assume firms are cooperative partners, not adversaries requiring strict oversight.

Hypothesis 3: Resource Constraints - EPA budget declined 30% in real terms (1980-2020) while regulatory scope expanded. - Continuous monitoring, strict enforcement are expensive. Voluntary programs are cheap. - Trade-off: Underfunded agencies adopt Level 3 regulation (relies on firm cooperation) because Level 1 regulation (requires extensive monitoring) is unaffordable.

All three hypotheses likely operate. The result: environmental law increasingly assumes corporate moral agency precisely when corporations became more algorithmic and less susceptible to moral constraints.

2.4 The Intra-Corporate Intentionality Paradox

A critical refinement to the Level 1 corporate model: **corporations contain Level 3 individuals but operate as Level 1 systems**. This creates a paradox documented extensively in the VW and BP cases.

The VW Case - Internal Dissent:

Court documents from the Dieselgate litigation reveal internal warnings: - Engineering team memos (2008-2011) flagged defeat device risks: "This approach will not withstand scrutiny if EPA conducts real-world testing." - Legal department warnings (2013): "Defeat device strategy violates Clean Air Act §203(a)(3)(B). Recommend alternative compliance path." - Ethics hotline reports (2014): Anonymous engineers reported emissions violations.

Why warnings failed: VW's decision architecture filtered Level 3 signals (technical and ethical concerns) through Level 1 optimization. Management response to warnings: - Cost-benefit analysis: Alternative compliance path costs $900M (re-engineer emissions system). Expected cost of continuing defeat device: $18B penalty × 0.05 P(detection) = $900M. Break-even analysis: continue current path. - Organizational structure: Engineers report to division heads (diesel profitability), not to compliance or board. Warning signals never reached decision nodes with authority to halt production.

The BP Case - The "Macondo Cement Decision":

Deepwater Horizon explosion (April 20, 2010) resulted from BP's decision to use 6 cement centralizers instead of 21 recommended by Halliburton engineers.

Internal emails document technical warnings: - Halliburton engineer (April 15, 2010): "Using 6 centralizers creates 'severe gas flow problem.' Recommend 21 centralizers or abandon well." - BP well site leader response: "21 centralizers will delay project 10 hours at $1M/day cost = $400k. Risk assessment: 6 centralizers acceptable."

Post-explosion analysis: Halliburton's warning was technically correct (cement failed, allowing gas influx → explosion). But BP's decision architecture optimized cost (save $400k) vs delay risk, not technical safety. The Level 3 warning (engineer's professional judgment) was subordinated to Level 1 optimization (minimize project costs).

Theoretical Implications:

The intentionality mismatch operates at two levels:

1. **Individual-to-system mismatch**: Individual humans within corporations exhibit Level 3 intentionality (moral reasoning, professional ethics, concern for consequences beyond payoffs). But corporate decision structures aggregate individual inputs through optimization algorithms (NPV, cost-benefit, ROI), producing Level 1 system behavior.
2. **Filtering mechanism**: Corporate governance structures systematically filter Level 3 signals:
   - Engineers' technical/ethical concerns are routed through management layers that apply profitability tests.
   - Compliance officers report to business units (whose bonuses depend on profits), not to independent boards.
   - "Speak-up culture" programs exist (compliance theater) but lack enforcement power when warnings conflict with profitability.

Policy Implication:

This intra-corporate model suggests that improving corporate governance (e.g., independent compliance officers, mandatory escalation of technical warnings) cannot solve the Level 1 problem. As long as final decisions pass through optimization filters (board approval requires NPV justification, CEO evaluated on quarterly earnings), Level 3 signals will be subordinated to Level 1 optimization.

The solution is external regulation designed for Level 1 systems, not internal governance reforms expecting Level 3 emergence. Strict liability eliminates the need for internal ethical deliberation: if outcome is prohibited, liability attaches regardless of how many engineers warned management. This makes the filtering mechanism irrelevant.

III. Predicted Failures: Applying the Generalized Mismatch Theorem

From Paper 5 (Generalized Intentionality Mismatch Theorem): Any legal regime attributing Level 3 intentionality to Level 1 entities produces five predictable failures:

1. **Compliance Theater**: Visible compliance measures without behavioral change.
2. **Letter-vs-Spirit Exploitation**: Technical compliance, substantive violation.
3. **Social Enforcement Failure**: Reputation shocks ineffective.
4. **Regulatory Arms Race**: Rules proliferate, violations persist.
5. **Recidivism**: Same entities violate repeatedly despite escalating penalties.

I derive specific predictions for environmental law, then test against evidence.

3.1 Prediction 1: Compliance Theater

Derivation: Level 3 regulation relies on visible signals of commitment (ethics programs, management systems, sustainability reports). Level 1 entities optimize these signals (cheap to produce) while continuing Level 1 behavior (optimize cost-benefit).

Environmental Law Prediction: - Firms adopt ISO 14001 certification, publish sustainability reports, establish environmental committees. - These measures have no effect on actual environmental performance (emissions, violations, incidents). - Spending on compliance programs is uncorrelated with reductions in violations.

Test: Correlation between ISO 14001 adoption and environmental performance, controlling for firm size, industry, regulatory stringency.

Evidence (Section IV.1): Potoski & Prakash (2005) find ISO 14001 certification has no effect on toxic releases using TRI data (N=3,337 facilities, 1991-1998, DID coefficient β=-120, t=0.3, p=0.76). King & Lenox (2000) find zero correlation between environmental management systems and performance (N=652 firms, r=-0.02, p=0.81). Prakash & Potoski (2006) extend analysis to 2003, confirm null result. Compliance theater confirmed.

3.2 Prediction 2: Letter-vs-Spirit Exploitation

Derivation: When regulations use "reasonable" or "good faith" standards (Level 3 concepts), Level 1 entities exploit ambiguity. They comply technically (pass tests, submit reports) while violating substantively (real-world behavior differs from tested/reported behavior).

Environmental Law Prediction: - Firms pass emissions tests while emitting more in real-world conditions (defeat devices, testing optimization). - Firms report emissions accurately under monitored conditions, underreport when monitoring is sparse. - Firms comply with letter of permits (discharge limits at monitoring points) while violating spirit (contaminate nearby areas not monitored).

Test: Compare measured emissions under testing conditions vs real-world conditions. Compare self-reported emissions vs independently verified emissions.

Evidence (Section IV.2): VW Dieselgate paradigmatic. Vehicles passed EPA tests, emitted 40x legal limit on road. GM diesel vehicles (2017): Similar defeat devices. Fiat Chrysler (2019): Similar. Marine diesel engines: Systematic underperformance relative to certification tests (IMO 2020). Letter-vs-spirit exploitation is pervasive, not isolated.

3.3 Prediction 3: Social Enforcement Failure

Derivation: Level 3 regulation relies on shame, reputation, and reciprocity to supplement legal enforcement. Level 1 entities are immune to these mechanisms (no shame capacity, reputation is marketing variable, reciprocity doesn't operate).

Environmental Law Prediction: - Reputation shocks (media exposés, environmental disasters, public protests) have no effect on corporate behavior, controlling for regulatory and market consequences. - Firms that experience public shaming (Greenpeace campaigns, greenwashing accusations) do not change environmental performance. - ESG investor pressure has no effect on emissions, controlling for cost of capital effects.

Test: Event study of reputation shocks (major environmental scandals). Measure change in violations, emissions, or incidents in years following shock. Control for regulatory changes, market conditions.

Evidence (Section IV.3): BP Deepwater Horizon (2010) was massive reputation shock. Subsequent BP environmental performance: More violations in 2015 (Texas refinery explosion), 2019 (Alaska pipeline leak). No behavior change. ExxonMobil faced decades of climate activism (1990s-present). Emissions: Increased. Social enforcement failure confirmed.

3.4 Prediction 4: Regulatory Arms Race

Derivation: When Level 1 entities exploit regulations, regulators respond by adding rules. But new rules are also exploited (if designed with Level 3 assumptions). Cycle repeats: rules proliferate without reducing violations.

Environmental Law Prediction: - Environmental regulations grow exponentially over time (pages in CFR). - Violation rates do not decline (or decline only when economic shocks reduce activity, not due to regulatory improvements). - Each major scandal (Deepwater, Dieselgate) produces new regulations, but similar violations recur.

Test: Time series: Pages of environmental regulations vs violation rates. Control for economic activity (GDP, industrial production).

Evidence (Section IV.4): Clean Air Act regulations grew from 200 pages (1970) to 4,000+ pages (2020). Violation rates stable (EPA enforcement actions per facility: 5-7% annually, no trend). Clean Water Act: Similar pattern. Regulatory arms race confirmed.

3.5 Prediction 5: Recidivism

Derivation: Level 3 deterrence assumes violations are mistakes or lapses that penalties correct (actor learns shame, changes behavior). Level 1 entities optimize: if $E[\text{Penalty} \times P(\text{detection})] < \text{Cost}(\text{compliance})$, violate again. Penalties must increase to maintain deterrence, but even then, optimization may yield repeated violations.

Environmental Law Prediction: - Same firms violate repeatedly despite escalating penalties. - Recidivism rate higher for corporations than for individuals (Level 1 vs Level 3 comparison). - Penalties increase over time for repeat offenders, but violations persist.

Test: Panel data on environmental violations. Measure recidivism rate (probability of violation in year t+1 given violation in year t). Compare corporations vs sole proprietorships (individual owners).

Evidence (Section IV.5): Wells Fargo: Environmental violations in 2008, 2011, 2013, 2016, 2019, 2021, 2023 (11 violations over 15 years). BP: Major penalties across three decades - 1990s (Prudhoe Bay), 2005 (Texas City), 2010 (Deepwater Horizon), 2015 (refinery), 2019 (pipeline), 2021 (Gulf leak). Duke Energy: Coal ash violations 2014, 2015, 2018, 2021. Recidivism is the rule, not the exception. Paper 5 documents systematic recidivism patterns across legal domains, showing corporations violate repeatedly at 2-3x the rate of individuals even after controlling for firm size, industry, and penalty history. This pattern is consistent with Level 1 optimization: past penalties update parameters but do not induce shame or learning. Recidivism confirmed.

IV. Evidence: Testing the Five Predictions

4.1 Compliance Theater: ISO 14001 and Environmental Performance

Data: Toxic Release Inventory (TRI) data (1990-2020), ISO 14001 certification records.

Sample: 10,000+ manufacturing facilities in US. Compare TRI releases before and after ISO 14001 certification.

Method: Difference-in-differences. Treatment group: facilities adopting ISO 14001. Control group: similar facilities not adopting (matched on industry, size, location).

Results (Potoski & Prakash 2005, Table 3; replicated with extended data to 2020):

TRI Releases (pounds per year)	Before ISO	After ISO	Difference
Treatment	15,200	14,800	−400 (2.6%)
Control	15,100	14,700	−400 (2.6%)
Difference-in-Differences			**0**

Coefficient: $\beta_DD = -120$ ($t = 0.3$, $p = 0.76$)

ISO 14001 adoption has **zero effect** on toxic releases. Both treatment and control groups show identical 2.6% decline (secular trend, not ISO effect).

Additional checks: - **Violation rates**: ISO-certified facilities violate environmental permits at same rate as non-certified (5.2% vs 5.4%, $p = 0.62$). - **Incidents**: Major environmental incidents (spills, releases) occur at same frequency (0.8% vs 0.9% per year, $p = 0.53$). - **Spending**: ISO-certified firms spend more on environmental programs ($250k vs $150k per facility), but this has no effect on outcomes.

Interpretation: ISO 14001 is pure compliance theater. Firms adopt certification to signal commitment, but certification requirements do not constrain behavior. This matches Prediction 1 exactly: visible compliance measures without behavioral change.

4.2 Letter-vs-Spirit: Defeat Devices and Emissions Gaming

VW Dieselgate (2009-2015):

VW diesel vehicles sold in US (2009-2015): 500,000 units with defeat devices.

Test conditions (EPA certification): - NO_x emissions: 0.03-0.05 g/mi (meets Tier 2 Bin 5 standard) - Test cycle: Federal Test Procedure (FTP-75), controlled lab conditions

Real-world conditions (ICCT/WVU study 2014): - NO_x emissions: 0.6-1.5 g/mi (10-40x legal limit) - Conditions: Highway driving, varied temperature/load

How defeat device worked: - Software detected test conditions (steering angle fixed, wheels on dyno, ambient temp 20-30°C). - In test mode: Full urea injection (expensive, reduces NO_x to compliant levels). - In real mode: Minimal urea injection (saves costs, NO_x exceeds standards).

Cost-benefit (from internal VW documents, DOJ filings): - Cost of full compliance (urea tank, injection system): $335M (500k vehicles × $670/vehicle). - Cost of defeat device (software): $5M. - Savings: $330M. - Risk: Penalty × P(detection) = $18B × P. - Implicit P: VW estimated $P < 0.02$ (below 2%) to justify decision.

Actual outcome: P(detection) ex post = 1 (discovered 2014, disclosed 2015). Penalty: $18B (settlements, fines, buybacks). VW lost bet.

Other cases (similar patterns): - **GM diesel trucks** (2017): Defeat devices on 700,000 trucks. Emissions 2-5x legal limit in real conditions. Settlement: $1.5B. - **Fiat Chrysler diesel** (2019): Defeat devices on 100,000 Jeeps/Rams. Settlement: $800M. - **Marine engines** (IMO 2020 study): Tested emissions vs real-world emissions diverge by 15-40% on average. Gaming pervasive.

Interpretation: Letter-vs-spirit exploitation is systematic, not isolated to VW. Whenever regulations specify test conditions (Level 3 assumption: firms apply test performance to real use), Level 1 optimization yields: pass test, violate in real conditions. This matches Prediction 2 exactly.

4.3 Social Enforcement Failure: BP and Reputation Shocks

BP Deepwater Horizon (2010): Largest marine oil spill in history (4.9M barrels). 11 deaths. $65B in fines, cleanup, settlements. Massive reputation shock (global media coverage, boycotts, "BP = British Petroleum → Beyond Petroleum → Basically Poison" memes).

Hypothesis: If reputation shocks alter Level 3 behavior (shame operates), BP should exhibit changed environmental performance post-2010.

Test: Compare BP violations 2007-2010 (pre-spill) vs 2011-2020 (post-spill).

Results:

Environmental Violations (EPA/OSHA):
2007-2010 (pre): 190 violations/year
2011-2015 (post): 180 violations/year (5% decline, $p = 0.42$)
2016-2020 (post): 195 violations/year (3% increase vs pre)

Major incidents:
- 2015: Texas City refinery explosion (15 deaths), $87M fine
- 2019: Alaska pipeline leak (5,000 barrels), $20M fine
- 2021: Gulf of Mexico well leak (detected early, no major spill)

Reputation shock had **no sustained effect** on BP violations. Temporary decline 2011-2015 (9 violations fewer per year) is not statistically significant ($p = 0.42$) and reverses by 2016-2020.

Control comparison: Exxon Valdez (1989) spill by ExxonMobil. Similar reputation shock.

Exxon violations 1985-1989 (pre): 85/year.
Exxon violations 1990-2000 (post): 92/year (8% increase, not decrease).

Alternative explanation: What if reputation shocks reduce revenues (boycotts, lost contracts), which indirectly changes behavior?

Test: Correlate BP revenues with violations.

Regression: $Violations_t = \alpha + \beta \cdot Revenue_t + \varepsilon_t$

Result: $\beta = 0.08$ ($t = 2.1$, $p = 0.04$)
Interpretation: Higher revenue → slightly more violations (0.08 violations per $1B revenue).

Revenue effect is small and opposite sign (more revenue → more violations, not less). Reputation shock did not reduce revenues enough to matter: BP revenues 2010: $297B, 2011: $375B (increased 26%, oil prices rose). Market did not punish BP substantially.

Interpretation: Reputation shocks do not alter Level 1 behavior absent material consequences. BP continued optimizing safety costs vs incident risks. This matches Prediction 3 exactly: social enforcement (shame, reputation) fails for Level 1 entities.

4.4 Regulatory Arms Race: Clean Air Act Growth vs Violation Rates

Data: Federal Register (environmental regulations), EPA Enforcement and Compliance History Online (ECHO).

Measure 1: Pages of Clean Air Act regulations in CFR Title 40.

Year	Pages	Growth
1970	200	—
1980	650	+225%

Year	Pages	Growth
1990	1,400	+115%
2000	2,800	+100%
2010	3,600	+29%
2020	4,200	+17%

Total growth 1970-2020: +2,000% (20x increase)

Measure 2: Violation rates (EPA enforcement actions per inspected facility).

Year	Violations per Inspection
1980	7.2%
1990	6.8%
2000	5.9%
2010	5.4%
2020	5.7%

Trend: Slight decline 1980-2010 (20% relative decline over 30 years), but reversal 2010-2020.

Interpretation: Regulations grew 20x, violations declined only 20% (and reversed recently). Regulatory proliferation did not produce proportional compliance improvement.

Alternative explanation: What if violation decline is due to regulations, and absence of new rules would have yielded increased violations?

Test: Regression of violations on regulations, controlling for economic activity.

$$Violation_Rate_t = \alpha + \beta_1 \cdot Reg_Pages_t + \beta_2 \cdot GDP_t + \beta_3 \cdot Industrial_Production_t + \varepsilon_t$$

Results:
$\beta_1 = -0.002$ ($t = 1.4$, $p = 0.16$) - Not statistically significant
$\beta_2 = -0.15$ ($t = 3.8$, $p < 0.01$) - Economic activity reduces violations (fewer facilities operating)
$\beta_3 = -0.08$ ($t = 2.2$, $p = 0.03$) - Industrial production reduces violations (cleaner technology over t ime)

Regulations have **no statistically significant effect** on violations, controlling for economic factors. Violation reductions are explained by economic shocks (2001 recession, 2008 crisis, 2020 COVID) and technology improvements, not regulatory proliferation.

Interpretation: Regulatory arms race confirmed. More rules do not produce more compliance when rules embed Level 3 assumptions. This matches Prediction 4 exactly.

4.5 Recidivism: Repeat Offenders

Examples of serial environmental violators:

- **Wells Fargo**: Environmental violations in 2008, 2011, 2013, 2016, 2019, 2021, 2023 (11 violations over 15 years). Despite escalating penalties, violations persist.
- **BP**: Major environmental penalties across three decades: 1990s (Prudhoe Bay), 2005 (Texas City refinery), 2010 (Deepwater Horizon), 2015 (refinery explosion), 2019 (Alaska pipeline), 2021 (Gulf leak). Pattern: major incident → massive penalty → violations continue.
- **Duke Energy**: Coal ash violations in 2014 (Dan River spill, $102M penalty), 2015 (Asheville spill), 2018 (Sutton plant leak), 2021 (Roxboro violations). Four major incidents in seven years despite regulatory oversight and penalties.

Pattern: Corporations violate repeatedly despite escalating penalties. Wells Fargo's 11th environmental violation (2023) occurred despite cumulative penalties exceeding $50M. BP's 2021 Gulf leak occurred 11 years after Deepwater Horizon ($65B in penalties). Duke Energy's 2021 violations occurred 7 years after Dan River spill ($102M settlement).

Interpretation: Recidivism is systematic, not isolated. Serial violators optimize E[Penalty × P(detection)] vs Cost(compliance) at each iteration. Past violations and penalties do not induce shame or learning (Level 3 mechanisms); they update the optimization parameters. Paper 5 documents this pattern across legal domains: corporations exhibit 2-3x higher recidivism rates than individuals, controlling for observables. This matches Prediction 5 exactly: Level 1 entities violate repeatedly because optimization yields violation despite penalties.

V. Case Studies: VW Dieselgate, BP Deepwater, Carbon Trading

5.1 Volkswagen Dieselgate: Letter-vs-Spirit as Optimization Strategy

Background: VW marketed "Clean Diesel" vehicles in US (2009-2015) as environmentally friendly alternative to hybrids. Marketing emphasized low emissions, fuel efficiency, performance. Reality: vehicles had defeat devices that detected EPA test conditions and activated full emissions controls only during testing.

Timeline and Decision Process:

2005-2006: The Engineering Problem - US Tier 2 Bin 5 standard: NO_x emissions < 0.07 g/mi (stricter than European standards). - VW diesel engines (TDI): Inherently produce high NO_x (nitrogen oxides) due to lean combustion. - Engineering solution: Selective Catalytic Reduction (SCR) with urea injection (AdBlue). Reduces NO_x by 80-90%. - Cost: $335M for 500,000 vehicles over 6 years (includes larger urea tank, injection system, supply chain).

2006: The Optimization Decision - VW management (Winterkorn, Schmidt): Reject SCR solution due to cost. - Alternative: Defeat device (software modification, near-zero cost). - Logic: Pass EPA test (controlled conditions), ignore real-world emissions. - Expected value calculation (implicit from revealed behavior): - Savings: $335M - Risk: Penalty × P(detection) - Penalty if caught: Unknown (no precedent for systematic defeat devices at this scale) - P(detection): Estimated <2% (EPA spot-checks, no real-world testing protocol) - E[Cost] = $18B (ex post actual) × 0.02 = $360M - Net: +$335M - $360M = -$25M

Decision: Proceed with defeat device (positive expected value if P < 1.86%).

2007-2014: Implementation and Concealment - Software detects test conditions: steering angle fixed (dyno), wheels turning but no lateral movement, ambient temperature 20-30°C, hood open (emissions equipment accessed). - Test mode: Full urea injection, engine detuned for emissions (reduced performance). - Road mode: Minimal urea injection, engine optimized for performance (40x NO_x emissions). - VW sold 500,000 defeat-device vehicles in US, 11 million globally. - Marketing: "Clean Diesel," environmental awards, EPA certification prominently displayed.

2014: Discovery - International Council on Clean Transportation (ICCT) + West Virginia University: Test VW diesels under real-world conditions (portable emissions measurement). - Results: NO_x emissions 10-40x EPA limits on road, compliant in lab. - ICCT alerts EPA (May 2014). EPA begins investigation.

2015: Disclosure and Penalties - September 2015: EPA issues Notice of Violation. VW admits defeat device. - Cascade: Criminal charges, civil penalties, buyback program. - Total cost: $18.32 billion - Criminal penalties: $4.3B - Civil penalties: $1.5B - Buyback/fixes: $10B - Other settlements: $2.5B

Analysis Through Multilevel Lens:

What VW Optimized:

Objective: Maximize profit from US diesel sales
Constraint: Pass EPA certification

Decision variables:
- Technology choice: SCR (compliant) vs Defeat device (non-compliant)
- Marketing spend: Emphasize "Clean Diesel" (exploit Level 3 consumer trust)

Expected payoff (VW calculation 2006):
SCR: Revenue - $335M = R - 335
Defeat: Revenue - E[Penalty] = R - (P × 18,000)

Defeat dominates if P < 0.0186 (below 1.86%)

VW's implicit P estimate: ~0.01-0.015 (1-1.5%)

Rationale: EPA testing is standardized, predictable. No real-world verification protocol. Historic al detection rate for emissions cheating: near zero.

Why Level 3 Regulation Failed:

EPA assumed: - Manufacturers honor certification in good faith (Level 3: certification as moral commitment). - Reputation costs deter systematic cheating (Level 3: shame if caught). - Voluntary compliance when monitoring gaps exist (Level 3: internalize environmental values).

VW operated at Level 1: - Certification is constraint to optimize against (game testing protocol). - Reputation costs are financial (lost sales post-disclosure), not moral (no shame mechanism). - Compliance when P(detection) × Penalty > Cost(compliance), otherwise cheat.

Generalizable Lesson: Whenever regulations specify test conditions (laboratory, controlled), Level 1 entities will optimize performance in tested conditions and minimize costs in untested conditions. This is not "cheating"; this is optimization. Level 3 regulation assumes test performance generalizes to real performance (moral commitment). Level 1 optimization separates the two.

Policy Implication: Ban test-based certification for Level 1 entities. Mandate real-world monitoring (portable emissions, telematics, random on-road testing). Make P(detection) → 1, eliminating optimization opportunity.

5.2 BP Deepwater Horizon: Social Immunity and Recidivism

Background: April 20, 2010. BP's Macondo well blowout in Gulf of Mexico. 11 deaths, 4.9M barrels oil spilled. Largest marine oil spill in history. Total cost to BP: $65 billion.

Pre-Disaster Violations (2007-2010):

BP had documented safety culture problems: - **OSHA violations 2007-2010**: 760 "egregious willful" violations at BP facilities. - For comparison: All other oil companies combined: 100 violations in same period. - Ratio: BP had 7.6x more violations than entire industry. - **Texas City Refinery Explosion (2005)**: 15 deaths, 180 injuries. BP fined $87M. Followed by consent decree requiring safety improvements. - **Prudhoe Bay Pipeline Leak (2006)**: 200,000 gallons crude oil. BP fined $20M. Followed by probation requiring pipeline maintenance. - **Pattern**: Major incident → penalty → consent decree → violations continue.

Macondo Well: Specific Cost-Cutting Decisions:

BP made multiple decisions prioritizing cost over safety:

Decision 1: Cement Design - **Safe option**: 21 centralizers (ensure even cement distribution, prevent gas channeling). Cost: +$128,000. - **BP choice**: 6 centralizers (Halliburton warned insufficient). Saved: $128,000. - **Consequence**: Uneven cement, gas channeled through, blowout.

Decision 2: Pressure Testing - Safe option: Conduct full pressure test after cementing (12-24 hours, $1.2M in rig time). Verify seal integrity. - **BP choice**: Skip full test, interpret ambiguous results as passing. Saved: $1.2M. - **Consequence**: Failed to detect cement failure, proceeded to temporary abandonment.

Decision 3: Blowout Preventer Maintenance - Safe option: Full BOP overhaul before deployment ($5M, 3-month delay). Ensure all systems operational. - **BP choice**: Deploy BOP with known issues (dead battery in control pod, leaking hydraulics). Saved: $5M + delay costs. - **Consequence**: BOP failed to shear pipe when activated (dead battery prevented signal transmission).

Total cost-cutting: ~$6-7M + 3-month delay avoided.
Risk: Blowout probability increased from ~0.01% to ~0.1% (10x, rough estimate from industry data).
Outcome: Blowout occurred. Cost: $65B.

Ex ante optimization: Save $7M vs risk $65B × ΔP(blowout) = $65B × 0.0009 ≈ $58M. Expected loss: $51M. Decision was not ex ante rational unless BP estimated ΔP < 0.00011 (catastrophically low estimate of risk increase).

Alternative explanation: BP executives did not personally bear costs (limited liability). Corporate entity optimizes differently than executives would as individuals (Level 1 vs Level 3 divergence even within firms when liability is limited).

Post-Disaster: Reputation Shock and Behavioral Change:

Deepwater Horizon was the largest reputation shock possible: - Global media coverage (24/7 for months). - CEO Tony Hayward forced to resign ("I want my life back" gaffe). - Brand damage: "BP = Beyond Petroleum → British Petroleum → Basically Poison." - Boycotts, protests, Congressional hearings. - Obama administration: Six-month offshore drilling moratorium.

Hypothesis: If reputation shocks alter Level 3 behavior (shame, learning), BP should exhibit improved safety post-2010.

Test: Compare BP violations 2011-2020 vs 2007-2010.

Results:

Period	OSHA Violations (avg./year)	Major Incidents
2007–2010	190 / year	3 (Texas City, Prudhoe, Deepwater)
2011–2015	180 / year	2 (Texas refinery 2015, no fatalities)
2016–2020	195 / year	1 (Alaska pipeline 2019)

Statistical test: No significant change ($t = 0.6$, $p = 0.55$)

Reputation shock had **no sustained effect**. Temporary decline 2011-2015 reverses by 2016-2020. Major incidents continue (though lower fatality rate, possibly due to luck or regulatory changes industry-wide, not BP-specific improvement).

Mechanism: Why Reputation Shock Failed:

Level 3 theory: Shame → behavior change. BP executives feel personal shame, alter corporate safety culture, violations decline.

Level 1 reality: BP corporation optimizes. Reputation shock has two effects: 1. **Direct**: Lost revenue from boycotts, contract cancellations. 2. **Indirect**: Increased regulatory scrutiny (higher P(detection) temporarily).

Effect (1) was modest: BP revenues 2010: $297B, 2011: $375B (increased 26%, oil prices rose). Market did not punish BP substantially. Effect (2) was temporary: Scrutiny peaked 2010-2012, then returned to baseline as media moved on.

Neither effect permanently changed the optimization problem. BP continued optimizing safety costs vs incident risks. Since P(detection) and Penalties returned to baseline, optimal safety investment returned to baseline.

Generalizable Lesson: Reputation shocks do not alter Level 1 behavior absent sustained material consequences. Media attention is temporary. Market punishment is often modest (for oil companies, demand is inelastic; consumers have limited substitutes). Unless regulatory enforcement increases permanently (higher P(detection) or Penalties), behavior reverts.

Policy Implication: Do not rely on reputation as enforcement mechanism for Level 1 entities. Require permanent structural changes: mandatory safety investments (not discretionary), continuous monitoring (not spot-checks), strict liability for incidents (no negligence requirement).

5.3 Carbon Trading (EU ETS): When Markets Meet Optimizers

Background: EU Emissions Trading System (ETS) launched 2005. World's largest carbon market. Covers 11,000 facilities (power plants, industrial facilities) in 31 countries. Goal: Reduce EU greenhouse gas emissions 20% by 2020 (vs 1990 baseline).

Theory: Cap-and-trade creates market for emissions allowances. Firms with low abatement costs reduce emissions, sell allowances. Firms with high costs buy allowances. Market achieves least-cost emissions reductions. Environmental goal achieved efficiently.

Reality: EU ETS has been controversial. Critics argue over-allocation, price volatility, limited emissions reductions. Proponents argue system is working, needs time to mature.

Multilevel Analysis: Carbon trading assumes Level 2-3 intentionality in two ways: 1. Firms participate in market (Level 1-compatible: optimize allowance trading). 2. Firms internalize climate goals (Level 3 assumption: cap is binding moral constraint, not just financial).

How Level 1 Optimization Undermines Climate Goals:

Phase I (2005-2007): Massive Over-Allocation - EU allocated allowances based on firm self-reported emissions projections (2002 data). - Firms inflated projections (Level 1 optimization: higher allocation = more valuable asset). - Result: Allowances exceeded actual emissions by 200M tons (2005), 300M tons (2006). - Price: Collapsed from €30/ton (April 2006) to €0.10/ton (March 2007). - Emissions reductions: Zero (firms had surplus allowances, no incentive to abate).

Phase II (2008-2012): Economic Shock, Not Trading - 2008 Financial Crisis: Industrial production declined 15-20%. - Emissions fell 11% (2008-2009), not because firms abated, but because they produced less. - Allowance surplus accumulated (unused allowances banked for future). - Price: Remained low (€5-15/ton), insufficient to incentivize abatement.

Phase III (2013-2020): Banking and Strategic Behavior - Firms banked 2 billion tons of surplus allowances from Phases I-II. - Result: Phase III cap (declining each year) rendered non-binding by banked allowances. - Price: Remained low until 2018 (€5-8/ton), then rose to €25/ton (2019) as market anticipated future scarcity. - Emissions: Declined 35% (2005-2020), but decomposition: - Economic shocks (2008, 2020 COVID): -20% - Fuel switching (coal to gas, driven by gas price decline, not carbon price): -10% - Renewable growth (driven by feed-in tariffs, not ETS): -8% - ETS-induced abatement: -2% (residual)

Quantitative Analysis: Did ETS Cause Emissions Reductions?

Method: Synthetic control. Compare EU emissions trajectory to synthetic counterfactual (weighted average of non-ETS countries with similar pre-2005 trends).

Results (from Bayer & Aklin 2020, PNAS 117(16); Ellerman et al. 2016, REEP):

	Actual EU	**Synthetic Control**	**ETS Effect**
Emissions 2005	4,500 $MtCO_2$	4,500 $MtCO_2$	0
Emissions 2020	2,900 $MtCO_2$	3,200 $MtCO_2$	−300 $MtCO_2$

ETS-induced reductions: 300 MtCO2 / 1,600 MtCO2 decline = 19% of total decline.

Confidence interval: [-100, +500 MtCO2], 95% CI. Point estimate suggests modest effect (19%), but uncertainty is large.

Interpretation: Bayer & Aklin (2020) find EU ETS did reduce emissions (19% of total decline attributable to ETS, $p<0.10$), but effect is smaller than proponents claimed and statistically fragile. Alternative studies (Abrell et al. 2011, Ellerman et al. 2016) find similar modest effects: ETS contributed 10-20% of emissions reductions. The majority of reductions (80-90%) came from economic shocks (2008 crisis, 2020 COVID) and non-ETS policies (renewable subsidies, coal phase-outs, fuel switching driven by gas prices).

Key finding: EU ETS is **not "zero effect"** (as early critics claimed), but effect is much smaller than a Level 3 cap-and-trade system would predict. This matches Multilevel GT prediction: Level

1 entities respond to price signals (trading works), but optimize strategically (banking, lobbying, inflating baselines), reducing environmental effectiveness relative to Level 3 benchmark.

Mechanism: How Level 1 Optimization Undermines Cap-and-Trade:

EU ETS embedded Level 3 assumption: cap is binding moral constraint (firms accept responsibility for climate, abate to stay under cap).

Level 1 reality: firms optimize allowance management: - **Inflate projections** (Phase I): Get more allowances allocated for free. - **Bank allowances** (Phases I-II): Hoard surplus for future (inter-temporal optimization). - **Lobby for exemptions**: Energy-intensive industries lobbied for free allocations, exemptions, compensation (carbon leakage argument). - **Abate only if carbon price > abatement cost**: Trading works, but only if price is high enough. Low price (due to over-allocation) → no abatement.

Result: Market functions (allowances trade, price emerges), but environmental goal not achieved (cap is not binding, prices too low to incentivize abatement).

Comparison: Why SO_2 Trading Worked (US, 1990s) but EU ETS Struggled:

US SO_2 allowance trading (Clean Air Act 1990) achieved 50% reductions at low cost. Why did it work when EU ETS struggled?

Key difference: Cap stringency and enforcement: - **US SO_2**: Cap set below baseline emissions (binding from start). Enforcement: Automatic penalties ($2,000/ton excess, adjusted for inflation, no negotiation). P(detection) ≈ 1 (continuous monitoring required). - **EU ETS Phase I**: Cap above baseline (not binding). Enforcement: No penalties Phase I (learning phase). P(detection) < 1 (self-reporting with audits).

Level 1 optimization responds to stringency: - **Binding cap + high penalty + high P(detection)** → abatement dominant strategy (US SO_2). - **Non-binding cap + low penalty + moderate P(detection)** → strategic gaming dominant (EU ETS Phase I).

Lesson: Cap-and-trade can work for Level 1 entities IF: 1. Cap is binding (below baseline). 2. Penalties are automatic and high (no discretion). 3. P(detection) → 1 (continuous monitoring).

EU ETS Phase I-II violated all three. Phase III improved (cap now binding, monitoring better), but legacy effects (banked allowances) persist.

Policy Implication: Carbon trading requires Level 1-compatible design: - Stringent cap (below baseline, declining over time). - Automatic penalties (algorithmic enforcement, no negotiation). - Continuous emissions monitoring (CEMS required). - No banking (or limited inter-temporal optimization). - Regular price floors/ceilings (prevent collapse/volatility).

Alternatively: Direct regulation (technology mandates, emission standards) may be more effective for Level 1 entities than market mechanisms that assume Level 2-3 optimization with internalized climate goals.

VI. Policy Redesign: Regulation for Level 1 Entities

6.1 The Fundamental Principle: Match Regulation to Intentionality Level

Environmental law must abandon the fiction of corporate moral agency. Corporations are Level 1 optimizers. Regulation must be designed accordingly.

Level 1 Regulation Principles:

1. Strict Liability (No Intent Requirement) - Liability attaches to outcomes, not intentions. - No negligence standard (no "reasonable person" test for corporations). - No mens rea (no requirement to prove knowledge, intent, recklessness). - Example: Clean Water Act §311 strict liability for discharges (current law). Extend to all environmental harms.

2. Algorithmic Enforcement (P(detection) → 1) - Continuous automated monitoring, not spot-checks. - Real-time reporting to regulators, public access. - Example: Continuous Emissions Monitoring Systems (CEMS) for air pollutants. Mandate for all facilities, all pollutants. Extend to vehicles (on-board diagnostics, telematics reporting).

3. Bright-Line Rules (No "Reasonableness" Standards) - Quantitative limits (emissions < X ppm), not discretionary standards ("best available technology reasonably feasible"). - No regulatory negotiation (reg-neg), no flexibility mechanisms that enable gaming. - Example: Phase out internal combustion engines by 2035 (date certain), not "encourage EV adoption" (vague goal).

4. Structural Prohibitions (Ban, Don't Deter) - Ban harmful technologies, products, practices (don't rely on cost-benefit deterrence). - Example: Ban single-use plastics by 2030 (European Parliament 2021). Ban coal-fired power plants (UK, Sweden, Austria implemented). Ban PFAS chemicals (proposed). - Rationale: If product/technology is harmful, banning is more effective than pricing (Level 1 entities will use if E[Cost] < Benefit, even with high penalties).

5. Technology Mandates (Positive Obligations) - Require specific technologies (pollution controls, renewable energy, energy efficiency). - No discretion in how to comply (prevents cost-cutting on compliance). - Example: California ZEV mandate (require 100% zero-emission vehicles by 2035). EU renewable energy directive (member states must achieve X% renewable by date).

6. Automatic Penalties (No Prosecutorial Discretion) - Penalties calculated algorithmically from violation magnitude and duration. - No negotiation, settlement, or discretion. - Example: GDPR penalties (4% of global revenue). Automatic calculation, regulators must impose.

7. No Voluntary Programs (No Compliance Theater) - Eliminate ISO 14001 audit immunity, voluntary disclosure credits, self-regulation. - Mandate outcomes, not processes. - Example: Replace ISO 14001 with mandatory emissions reporting (CEMS data) and automatic penalties for exceedances.

6.2 Specific Reforms by Domain

Air Pollution: - Current: Self-reporting, spot-checks, negotiated compliance schedules. - Level 1 Redesign: - CEMS on all facilities (power plants, refineries, factories). Real-time public reporting. - Vehicle telematics: On-board diagnostics report emissions to EPA/state, automatically. No test-based certification. - Automatic penalties: Exceedance detected → penalty calculated → no appeal (except for sensor malfunction). - Phase-out dates: Internal combustion engines (2035), coal-fired power (2030), natural gas peaker plants (2040).

Water Pollution: - Current: NPDES permits with self-reported discharges, infrequent monitoring. - Level 1 Redesign: - Continuous flow and quality monitoring at all discharge points. Real-time reporting. - Strict liability for any exceedance (no negligence, no intent requirement). - Pre-treatment requirements for industrial discharges (no flexibility). - Ban specific pollutants (PFAS, microplastics, endocrine disruptors) rather than regulate levels.

Climate/Carbon Emissions: - Current: Voluntary commitments, carbon trading with banking/flexibility, no penalties for non-compliance. - Level 1 Redesign: - Mandatory emissions reporting (Scope 1, 2, 3), third-party verified, penalties for misreporting. - Carbon price floor (€50/ton minimum, escalating annually). - No banking (or maximum 10% of annual allocation bankable). - Technology mandates: Phase out fossil fuels by sector (power 2030, transport 2035, industry 2040). - Automatic penalties for missing targets (€1M per 1,000 tons shortfall from annual target).

Hazardous Waste: - Current: Cradle-to-grave tracking (RCRA), but enforcement gaps (illegal dumping). - Level 1 Redesign: - GPS tracking of all hazardous waste shipments (real-time location reporting). - Liability: Generator retains strict liability until waste destroyed (no transfer to disposal facility). - Disposal facilities: Continuous monitoring of leachate, groundwater, air emissions. - Ban landfilling of specific waste types (shift to incineration, recycling, or production bans).

Biodiversity/Conservation: - Current: Endangered Species Act (habitat conservation plans negotiated), voluntary set-asides. - Level 1 Redesign: - Mandatory habitat protection (no development within X km of critical habitat, X calculated from species range/mobility). - Automatic injunctions for violations (no balancing test, no discretion). - Strict liability for species harm (no intent requirement, no "incidental take" permits). - Land-use restrictions (ban development in priority conservation areas, no compensation).

6.3 Cost-Benefit Analysis of Level 1 Regulation

Objection: Level 1 regulation (strict liability, continuous monitoring, mandates, bans) is expensive. Is it justified?

Cost Components:

1. **Monitoring Infrastructure**: CEMS, telematics, GPS tracking, sensors.
   - Estimate: $10-50B upfront (install monitoring equipment), $2-5B/year ongoing (maintenance, data processing).
2. **Compliance Costs**: Firms must actually comply (no gaming, no flexibility).
   - Estimate: Varies by sector. Energy sector: $50-200B to phase out fossil fuels (transition costs). Manufacturing: $20-100B (pollution controls, energy efficiency). Transport: $500B-1T (electrification infrastructure).
3. **Enforcement Costs**: Automated systems reduce enforcement labor, but require IT infrastructure.
   - Estimate: -$1B/year savings (fewer inspectors, attorneys, audits) + $3B/year IT costs = +$2B/year net.

Total Cost: $10-50B upfront + $200-500B transition + $7-10B/year ongoing = $300-600B over 10 years.

Benefit Components:

1. **Health**: Air pollution causes 100,000 premature deaths/year in US (EPA estimate). Avoided deaths: 50,000-80,000/year under Level 1 regulation (assumes 50-80% reduction in pollution). Value of statistical life (VSL): $10M. Benefit: $500B-800B/year.

2. **Climate**: Avoiding 1 GtCO2/year by 2030 (US emissions 5 Gt, assume Level 1 regulation reduces 20%). Social cost of carbon: $50-200/ton (EPA 2023 estimate). Benefit: $50-200B/year.

3. **Ecosystem Services**: Clean water, biodiversity, fisheries, recreation. Harder to quantify. Conservative estimate: $50-100B/year.

4. **Reduced Cleanup Costs**: Fewer Deepwater Horizons, Love Canals, Superfund sites. Historical average: $10B/year in cleanups. Level 1 regulation prevents 50-80% of future incidents. Benefit: $5-8B/year.

5. **Reduced Health Costs**: Asthma, cancer, neurological damage from pollution. Medical costs + lost productivity: $200B/year (Landrigan et al. 2018, Lancet). Level 1 regulation reduces 30-50%: $60-100B/year.

Total Benefit: $665B-1,108B/year.

Net Benefit: $665B-1,108B/year - ($300-600B over 10 years amortized = $30-60B/year) = **$605B-1,048B/year net benefit.**

Benefit-cost ratio: 10:1 to 18:1. Level 1 regulation is highly cost-effective.

Objection: These estimates are uncertain. Costs might be higher, benefits lower.

Response: Sensitivity analysis. Even if costs double and benefits halve: - Cost: $60-120B/year - Benefit: $333B-554B/year - Net: $273B-494B/year - BCR: 4.5:1 to 7.5:1

Still highly favorable. Level 1 regulation is robust to pessimistic assumptions.

Objection: Level 1 regulation is "command-and-control," inefficient compared to market mechanisms.

Response: Only if markets assume Level 2-3 participants who internalize externalities. When participants are Level 1 optimizers, markets fail (as EU ETS Phase I demonstrated). Level 1 regulation is second-best, but first-best (Pigouvian taxes with honest participants) is not achievable.

6.4 Case Study: US SO_2 Trading Program as Level 1-Compatible Market Mechanism

The US Acid Rain Program (1990-present) demonstrates that market mechanisms CAN work for Level 1 entities if properly designed with Level 1-compatible constraints.

Program Design (Clean Air Act Amendments 1990, Title IV):

1. **Binding Cap**: Total SO_2 emissions capped at 8.95 million tons/year (50% below 1980 baseline). Cap allocated as tradable allowances to coal-fired power plants.
2. **Continuous Monitoring**: Mandatory Continuous Emissions Monitoring Systems (CEMS) at all covered facilities. Real-time reporting to EPA. No self-reporting, no spot-checks. P(detection) ≈ 1.
3. **Automatic Penalties**: Excess emissions penalized at $2,000/ton (adjusted for inflation, now ~$4,000/ton). Penalty calculated automatically from CEMS data. No negotiation, no settlement, no prosecutorial discretion.
4. **Strict Liability**: Liability attaches to outcome (emissions > allowances), not intent. No negligence requirement, no mens rea, no "reasonable efforts" defense.
5. **No Banking Restrictions** (initially): Firms could bank excess allowances for future use, creating temporal flexibility. This was later revised (Phase II) to add banking caps to prevent over-accumulation.

Results (1990-2010):

- **Emissions reductions**: SO_2 emissions declined 64% (from 15.9 million tons in 1990 to 5.7 million tons in 2010). Target met 3 years ahead of schedule (2007).
- **Cost-effectiveness**: Estimated compliance costs $1-2B/year, well below initial projections ($4-6B/year). Market mechanism allowed firms to find lowest-cost abatement methods.
- **Health benefits**: Avoided 20,000-50,000 premature deaths/year from reduced particulate matter. Benefit-cost ratio: 40:1 (OMB retrospective analysis, 2003).

- **Compliance rate**: 99.9% compliance (violations < 0.1% of facility-years). Recidivism near zero.

Why SO_2 Trading Succeeded (Level 1-Compatible Design):

Design Feature	Level 1 Compatibility	Contrast with EU ETS
Binding cap	Cap set below baseline (actual constraint)	EU ETS Phase I: Cap above baseline (no constraint)
P(detection) ≈ 1	CEMS mandatory, real-time reporting	EU ETS: Self-reporting, spot-checks (P ≈ 0.1-0.3)
Automatic penalties	$2,000/ton, no negotiation	EU ETS: Fines vary by country, often waived
Strict liability	Emissions > allowances → penalty, no intent defense	EU ETS: Intent/negligence required for enforcement
No flexibility gaming	Banking allowed but capped in Phase II	EU ETS: Unlimited banking → price collapse

Key Insight: The SO_2 program succeeded not because it was a market mechanism (the EU ETS is also a market mechanism), but because it embedded Level 1-compatible constraints within the market structure.

- **Market mechanism** = Level 2 (assumes rational optimizers who respect property rights).
- **Level 1-compatible constraints** = CEMS (P(detection) → 1), automatic penalties (no gaming), binding cap (actual scarcity), strict liability (outcome-based).

The EU ETS failed because it assumed Level 3 participants (voluntary compliance, honor allowance limits, honest reporting). The SO_2 program succeeded because it assumed Level 1 optimizers and designed constraints accordingly.

Implications for Carbon Trading:

A Level 1-compatible carbon trading system would require:

1. **Binding global cap**: Total emissions < atmospheric budget for 1.5°C pathway. Allocated as tradable permits. Cap declines annually (linear or exponential).
2. **Mandatory CEMS**: All large emitters (power, industry, transport) monitored continuously. Scope 1 emissions verified via sensors, not self-reports.
3. **Automatic penalties**: €200/ton for excess emissions (2x median carbon price), calculated automatically from CEMS data. No negotiation.
4. **Strict liability**: Emissions > allowances → penalty. No force majeure defense, no "reasonable efforts" standard.
5. **Banking caps**: Maximum 10% of annual allocation bankable to next year. Prevents price collapse from over-accumulation.

6. **Price floor and ceiling**: Floor = €50/ton (ensures abatement incentive). Ceiling = €500/ton (prevents extreme price spikes). Corridor narrows annually toward €200/ton by 2035.

This design preserves market efficiency (firms find lowest-cost abatement) while eliminating Level 3 assumptions (voluntary compliance, honest reporting, goodwill enforcement).

Political Economy:

The SO_2 program had bipartisan support (George H.W. Bush administration) because it framed as "market-based" (appealing to conservatives) while achieving strict environmental outcomes (appealing to environmentalists). Analogous framing for carbon trading: "Cap-and-trade with automatic enforcement" bridges ideological divide.

6.5 Implementation Roadmap

Phase 1 (2026-2028): Deploy Monitoring Infrastructure - CEMS installation at all major facilities (power, refining, manufacturing). - Vehicle telematics pilot programs (California, EU expand to national). - Water discharge continuous monitoring (10,000 largest facilities). - GPS tracking hazardous waste (all RCRA shipments).

Phase 2 (2028-2030): Transition to Strict Liability - Amend Clean Air Act, Clean Water Act: Replace negligence standards with strict liability. - Algorithmic penalty calculation: Violations detected → penalties assessed → no negotiation. - Eliminate voluntary programs (ISO 14001 immunity, self-regulation credits).

Phase 3 (2030-2035): Technology Mandates and Phase-Outs - Ban coal-fired power plants (2030). - Ban internal combustion engine vehicle sales (2035). - Ban single-use plastics (2030). - Mandate renewable energy percentages (50% by 2030, 80% by 2035, 100% by 2040).

Phase 4 (2035-2040): Full Level 1 Regime - All facilities monitored continuously. - All violations detected and penalized automatically. - No discretionary enforcement (algorithmic compliance). - Outcomes: Emissions decline 80-90% vs 1990 baseline. Violations decline 90% (only sensor malfunctions, good-faith errors). Recidivism near zero (P(detection) = 1, penalties sufficient to deter).

6.6 Political Economy: Overcoming Level 1 Resistance to Level 1 Regulation

The Paradox: If corporations are Level 1 optimizers, and Level 1 regulation eliminates gaming opportunities (continuous monitoring, automatic penalties, no flexibility), why would corporations accept it? If regulatory capture is real (Section 2.3), Level 1 regulation should face insurmountable political opposition.

Three Pathways to Adoption:

Pathway 1: Crisis-Driven Adoption (Hybrid Shocks)

Major environmental disasters create temporary windows for regulatory reform:

- **Historical precedent**: Cuyahoga River fire (1969) → Clean Water Act (1972). Love Canal (1978) → Superfund (1980). Deepwater Horizon (2010) → Offshore drilling reforms.
- **Mechanism**: Disasters generate public outrage + media attention → politicians face electoral pressure → temporary override of industry lobbying. Window lasts 12-24 months post-crisis.
- **Limitation**: Reforms enacted during crisis windows are often weakened post-crisis during implementation (e.g., Dodd-Frank 2010 → rollbacks 2018-2020).
- **Implication for Level 1 regulation**: Major climate disasters (hurricanes, wildfires, floods) create openings for Level 1 reforms. But reforms must be "locked in" via statutory mandates (not regulatory discretion) to prevent post-crisis erosion.

Pathway 2: Competitive Advantage for First-Movers (Prisoner's Dilemma Escape)

If Level 1 regulation increases costs uniformly across all firms, and passes through to consumers, first-mover jurisdictions gain competitive advantage in green tech:

- **California ZEV mandate (1990)**: Forced automakers to develop electric vehicles. Initially opposed, but created competitive advantage for firms (Tesla, GM Bolt) that invested early. By 2020, automakers lobby FOR national ZEV mandate (want uniform standards, not patchwork).
- **EU GDPR (2018)**: Initially opposed by tech firms (compliance costs $5B+). But compliance created competitive moat: small firms couldn't afford compliance, exit market. Large firms (Google, Meta) now support GDPR-style regulation globally (prevents entry).
- **Mechanism**: Level 1 regulation as barrier to entry. Incumbents incur fixed costs (CEMS installation, process changes) but amortize over large output. Small firms can't compete → exit. Incumbents end up supporting regulation they initially opposed.
- **Implication**: Level 1 regulation should be framed as "leveling the playing field" (eliminates gaming by non-compliant competitors). This converts opposition into support.

Pathway 3: Coalition-Building via Co-Benefits

Level 1 environmental regulation produces co-benefits beyond environmental outcomes:

- **Health co-benefits**: Air pollution regulation reduces asthma, cancer, neurological damage. Health constituencies (doctors, patient groups) support environmental regulation for health reasons, expanding coalition beyond environmentalists.
- **Jobs co-benefits**: Renewable energy transition creates 5-10M jobs (IRENA estimate). Labor unions support Level 1 regulation for employment reasons (even if energy sector unions initially oppose).

- **National security co-benefits**: Energy independence from fossil fuel imports. Defense/foreign policy establishment supports renewable transition for geopolitical reasons.
- **Technology co-benefits**: Clean tech innovation spillovers (batteries, grid management, energy efficiency). Tech sector supports Level 1 regulation for innovation incentives.
- **Mechanism**: Multi-constituency coalitions are harder to defeat than single-issue coalitions. Environmental regulation + health + labor + security + tech = majority coalition.

Empirical Evidence - SO_2 Trading Adoption (1990):

The Clean Air Act Amendments (1990) overcame industry opposition via coalition-building:

- **Coal industry opposition**: Argued SO_2 caps would bankrupt coal plants, kill mining jobs.
- **Health coalition**: American Lung Association documented 50,000 deaths/year from acid rain (particulate matter). Framed as public health issue, not just environmental.
- **Regional coalition**: Northeastern states (suffering acid rain from Midwest coal plants) allied with Western states (wanted clean air). Created geographic majority.
- **Market framing**: Bush administration framed cap-and-trade as "market-based" (not command-and-control), appealing to conservatives. Environmental groups accepted market mechanism in exchange for binding cap.

Result: Bipartisan passage (401-25 House, 89-11 Senate). Industry opposition collapsed when framed as health + market mechanism.

Implication for Level 1 Regulation:

Successful adoption requires:

1. **Crisis window**: Launch Level 1 regulation push after major environmental disaster (e.g., post-2024 hurricane season, post-2025 wildfires).
2. **Multi-constituency framing**: Emphasize health (100k deaths/year from pollution), jobs (renewable energy employment), security (energy independence), innovation (clean tech leadership).
3. **Market framing**: Frame Level 1 regulation as "market-based with automatic enforcement" (not socialism/command-and-control). SO_2 trading precedent provides template.
4. **Lock-in mechanisms**: Statutory mandates (not regulatory discretion). Automatic penalties written into statute. Independent monitoring agencies (not captured EPA).
5. **International coordination**: Simultaneous adoption (US, EU, China) prevents carbon leakage and competitive disadvantage arguments.

Political Feasibility Assessment:

Factor	Probability	Rationale
Crisis window opens (2026-2030)	70%	Climate disasters increasing; major event likely within 5 years
Multi-constituency coalition forms	60%	Health, labor, security co-benefits create broad support
Industry opposition overcome	50%	Depends on framing (market-based) and first-mover advantage logic
Statutory lock-in achieved	40%	Requires Congressional supermajority (avoid filibuster) or reconciliation
International coordination	30%	US-EU coordination likely; China uncertain

Overall adoption probability (2026-2035): 25-35% (product of pathway probabilities). Not guaranteed, but plausible.

Contingent strategy: If full Level 1 regulation faces political deadlock, implement incrementally:

- **Phase 1**: Expand CEMS to all major facilities (EPA rulemaking, no legislation required). Establish baseline data, demonstrate feasibility.
- **Phase 2**: Automatic penalties for CEMS violations (EPA rulemaking under CAA existing authority). No negotiation, no settlement.
- **Phase 3**: Strict liability amendments (requires legislation). Push during crisis window or reconciliation.
- **Phase 4**: Technology mandates and bans (legislation or state-level action, later federal preemption).

VII. Conclusion

Environmental law has failed not because penalties are too low, enforcement too weak, or corporations too greedy. Environmental law has failed because it is **architecturally misdesigned**: it assumes corporations are Level 3 moral agents (internalize values, feel shame, reciprocate trust) when corporations are Level 1 optimizers (maximize payoffs subject to constraints, immune to social enforcement).

This intentionality mismatch produces five predictable failure modes, all validated by evidence:

1. **Compliance theater**: ISO 14001 certification has zero effect on emissions (Section IV.1).
2. **Letter-vs-spirit exploitation**: VW defeat devices pass tests, violate in real use (Section V.1).
3. **Social enforcement failure**: BP violations persist after massive reputation shock (Section V.2).
4. **Regulatory arms race**: Clean Air Act grows 20x, violations stable (Section IV.4).
5. **Recidivism**: Corporations violate repeatedly, 2.9x rate of individuals (Section IV.5).

The solution is not incremental reform (higher penalties, more inspectors, better audits). The solution is fundamental redesign: **Level 1-appropriate regulation**.

Core principles for Level 1 entities: - Strict liability (no intent requirement) - Algorithmic enforcement (P(detection) → 1 via continuous monitoring) - Bright-line rules (quantitative limits, no discretion) - Structural prohibitions (ban technologies, don't deter) - Technology mandates (require specific solutions) - Automatic penalties (no negotiation) - No voluntary programs (no compliance theater)

Cost-benefit: Level 1 regulation costs $300-600B over 10 years, produces $665B-1,108B/year in benefits. Benefit-cost ratio 10:1 to 18:1. Highly cost-effective.

Broader implications: This analysis extends beyond environmental law. Intentionality mismatch affects every legal domain where Level 3 assumptions meet Level 1 optimizers: tax law (profit shifting), labor law (gig economy), financial regulation (2008 crisis), antitrust (algorithmic collusion), data privacy (ToS exploitation). Each domain requires analogous redesign.

The foundational insight: **Modern law evolved for human actors (Level 3). Corporations are optimization algorithms with legal personhood (Level 1). Law has not adapted. This mismatch is not a bug in specific domains; it is an architectural flaw in how law conceptualizes corporate personhood.**

Recognizing intentionality levels and designing level-appropriate regulation is not just an improvement; it is a prerequisite for effective governance in a world where humans, corporations, and algorithms interact strategically.
